

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Raybestos

Price and Quality Must Balance

The quality of the brake lining you sell must be consistent with the price you charge for it, or you will not be able to hold your trade.

This is so—and nobody knows it better than you. That Price and Quality must balance is just as true with net prices as it is with list prices.

What is the Quality of brake linings which list the same as RAYBESTOS, and in some cases higher, but are offered you at a lower net price?

What do you suppose is the lowest net price?

How do you know when you get it?

How long before juggled discount prices will affect you?

RAYBESTOS schedule of prices—both net and list—are fixed, uniform to all—and at all times consistent with RAYBESTOS Quality.

WITH FISK SERVICE

FISK TIRES

WITH FISK SERVICE

At New Low Prices

WE HAVE A BIG plant, big facilities, big volume in production and a big and growing organization that will enable us to continue to build tires of established Fisk Quality and to sell them at prices which set new and wonderful standards for value.

Note These Prices For Comparison

Size	Plain Tread Casing	Non-Skid Casing	Tubes
3 x 30	$ 9.00	$ 9.45	$2.35
3½ x 30	11.60	12.20	2.70
4 x 33	19.05	20.00	3.85
4 x 34	19.40	20.35	4.00
4½ x 36	27.35	28.70	5.20
5 x 37	32.30	33.90	6.25

"If You Pay More Than Fisk Prices You Pay For Something That Does Not Exist." Better Tires Cannot Be Bought At Any Price.

IN THE TIRE WORLD the name FISK stands for Quality, Mileage and Satisfaction. It stands for an organized service that is unequalled in the tire industry and for an ideal that is inspired by the belief that **satisfied customers** are of the first and greatest importance.

You Can Buy Fisk Tires At All Dealers

THEY JOIN US, in reducing the profits on the individual sale to the minimum, in their willingness to depend for success on the increased volume of business.

Don't Throw Away Your Half-Worn Tires

They're Still Good for 5,000 Miles

European Methods of Half-Soling Tires Makes Them Run 10,000 to 15,000 Miles. Signed Guarantee for 5,000 Miles Without Puncture. Skidding Rendered Impossible.

You Take No Risk—We Ship On Approval

The man who throws away his half-worn tires or sells them to the junk man for a few cents a pound is just as extravagant as the man who throws away his shoes when the first sole gets thin.

For over three years European motorists have been "half-soling" their tires, just as we half-sole our shoes. As a result, they are getting 10,000 to 15,000 miles out of ordinary pneumatic tires, while American motorists are getting from 3,000 to 5,000 miles—and what is just as important, they have almost entirely eliminated punctures, blow-outs and rim cuts with their ever constant dread. To say nothing of making skidding impossible.

Save $50 to $200 a Year

Figure this out by the individual—how it affects you—your pocketbook.

Every mile you travel on the bare tire is costing you from 1½c. to 4c. in tire wear alone, to say nothing of the lost time and expense for the repair of punctures and blow-outs.

Just stop for a moment and consider what it means to you to get 10,000, 12,000 or 15,000 miles out of your tires and at the same time drive your car without the constant nerve-racking dread of tire trouble and skidding.

In round numbers it means a saving of $50 to $200 each year—a saving sufficient to pay your gas and oil bills each month. Yet this saving is not all—the tire vacation and relief from skidding assured you certainly means a gratification which cannot be estimated in dollars and cents.

No More Skidding

Durable Treads are as sure footed as a Rocky Mountain burro, and they're supremely convenient.

They are studded with sharp-edged steel rivets which dig right down through the mud and slush and get to earth every time. In London and Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of the steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and—what is more important, you receive perfect non-skid service while your tires are protected instead of injured. They cover the tire completely, extending entirely around from rim to rim. Nothing can work its way in between. They afford a perfect protection—that's why we can guarantee them as we do.

No Matter How Cut or Worn They Are

No matter how cut or worn they are, you can get more mileage from them and the few cents the junk man would give you can be turned into dollars.

The strongest proof of the economy of Durable Treads is their unprecedented record of sales: 40% of the business comes direct from recommendations of users; in eight months the sale of Durable Treads increased over 700% in the United States alone.

Where is there an automobile accessory which has received such instant and country-wide endorsement?

Think of it—a 5,000 mile tire vacation—to be able to FORGET tires!

This is a pretty strong statement unsupported, but it's not merely a claim.

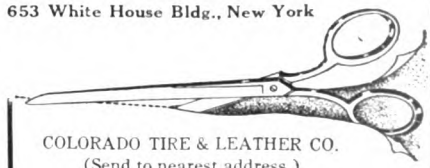
Durable Treads are delivered to you under a signed guarantee for 5,000 miles of wear without puncture.

This guarantee is an ironclad agreement—as good as a government bond and holds good whether your tires are new or old, tread worn, rut worn or rim cut

Special Discount Offer

To motorists in territory where Durable Treads are not as yet represented we offer a special introductory discount for advertising purposes, equal to the full dealer's profit.

We have made some strong statements in this advertisement. Make us prove them. You have everything to gain and absolutely nothing to lose, for all we ask is the opportunity to give you a demonstration at our own expense and risk.



We have a catalog, sample and copy of written guarantee ready to send and they're yours free for the asking.

Don't let the tires on your car run another week in "bare-footed" condition—don't wait until you get your next puncture or blow-out.

Fill out and mail the coupon right now and you will hear from us within a week; no expense and no obligation to you.

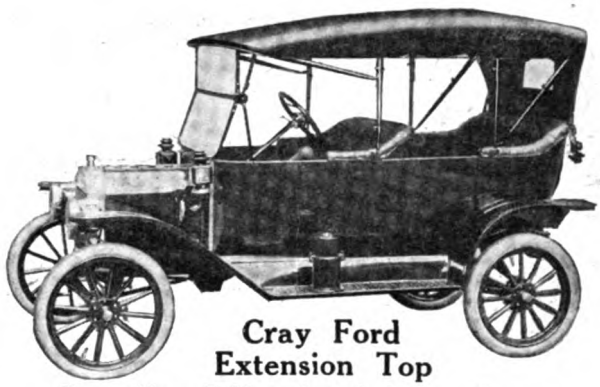
Push Cray Ford Tops Now and Double Your Profits

Here's a line you don't have to "talk up" to sell. It's got quality sticking out all over it. Whenever you see a Ford with an old, leaky, worn-out top, just remind the owner that you can furnish him a Cray Top complete with neat fitting side curtains, at a price so low he can't afford to do without one, and there ought to be a dozen or two jobs right in your locality, waiting to be sold. If you get busy you can sell them and if you sell the Cray top it's a **stay sold job.** Most garages overlook this profitable line—and few car owners know where to go to have new tops put on their machines. You can get the lion's share of the top business, and also many extra jobs for painting, repair work or auto supplies by putting forth a little extra effort right now, to let your customers know you can save them money on tops.

Cray Tops For Ford Cars

Made in Our Own Up-to-date Top Factory. Built Right Over Ford Body Frames—Guaranteed to Fit.



Cray Ford One-Man Top

The most easily operated One-Man Top made. Does not go up into the air when being folded, nor does it fall on the front seat, but maintains the same general level as when top is up and attached to windshield. Can be operated from outside, as well as inside of car. When up, top gives unobstructed side view from the driver's seat. It is staunch and rigid. Covered with mohair.

Made to fit 1913, 1914 and 1915 Ford Touring Cars only.

This actual photograph shows how easily the Cray One-Man Top can be raised and lowered. One man does the trick. Top is covered with Mohair. Side curtains are fastened inside. Has extra large celluloid lights in back and side curtains.

Cray Ford Extension Top

Heavy 32 oz. Rubber—Smooth Deck or Roof—Extra Quality Wood Bows—Best Grade Top Hardware · Shifting Handy Style Reinforced Bow Sockets—Large Celluloid Lights in Curtains—Heavy Harness Leather Straps—Best of Workmanship—Waterproof—Durable—Made to Measure—Fit Guaranteed—Quick Shipment.

Will fit 1912, 1913, 1914 and 1915 Model T Cars

Cray Slip Roof Outfit "A"

Consists of a new heavy rubber roof, quarters, back curtain and back stays, stitched and ready to slip over the old top frame. Easily put on. Makes an old top new at about one-third the price of a complete top. Made only for 1912, 1913 and 1914 Model T Touring Cars.

For best dealers' prices on our complete line of Ford Tops, Slip Roof Outfits, Recovering old Tops, and a full line of Auto Accessories, see our

FREE BOOK for Auto Repair Men

This Auto Repairers' Guide and Price Maker is issued in the interest of automobile repairers, dealers and garage men—it's free to the trade and sent to them only.

Contains 512 pages of bargains—about 3000 illustrations—a complete auto repairers' guide and price maker—quotes lowest wholesale prices on first quality automobile supplies, auto repairers' tools, tool kits, spark plugs, horns, lamps, pumps, springs, forgings, batteries, coils, switches, Ford tops and accessories, and in fact everything used on an auto.

Fill in, sign and mail the coupon.

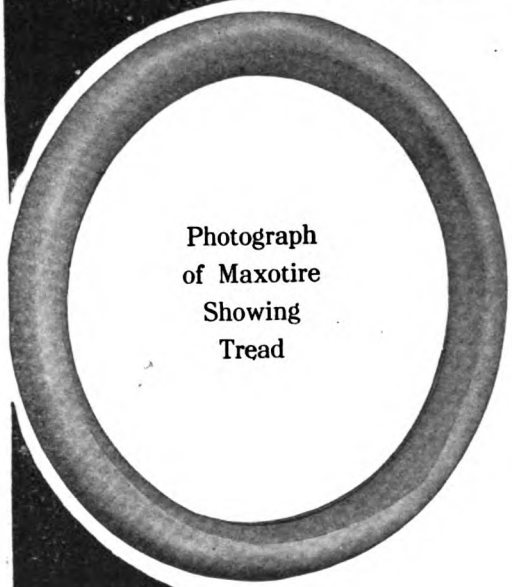
Your tires may often be worn down like this without danger of blowout or tire trouble.



You may now run your tires until there is little left of the outside shoe.

The secret of it all lies in the MAXOTIRE which is in reality a perfect tire having a rubber tread, fabric and bead. The MAXOTIRE is so scientifically constructed that it fits the inside of your tire perfectly. It leaves ample space for your inner tube and protects it from being damaged in any way.

The layer of very tough rubber covering the tread surface of the MAXOTIRE acts as a cushion between the MAXOTIRE and the outside shoe.

When the tire strikes a stone or is put to any great strain, this elastic rubber between the two fabric bodies of the tire and the MAXOTIRE equalizes the strain of both and prevents fabric breaks as well as blowouts.

·MAXOTIRES·

Photograph of Maxotire Showing Tread

Nothing like the MAXOTIRE has ever been sold before

Rubber-treaded MAXOTIRES make your tires practically puncture-proof. Tacks cannot reach the tube, while spikes or nails are invariably turned aside.

When MAXOTIRES are placed in tires this tough rubber tread comes in contact with the inner surface or fabric of the tire. This rubber tread clings to the tire like an overshoe to the sidewalk. There is, consequently, no friction; no heat generated; and no chance for the MAXOTIRE to slip and injure the inner tube.

Smaller inner tubes are not required for use with MAXOTIRES; however, they can be used with success at a saving to you of about 25% of their cost.

USE MAXOTIRES

HAVE TWO TIRES PROTECTING YOUR INNER TUBES

Take No Chances This Spring. Equip your tires with MAXOTIRES before taking your car out. While your car has been standing idle during the **winter,** your tires have deteriorated. They are in much worse condition than the outside appears. Tires blow out in nearly every case before the tread is hardly worn. This is due entirely to internal weakness which no one is able to discover.

MAXOTIRES will make your tires **trouble proof** during the coming season and enable you to get the full wear out of every tire. They are not an experiment but the result of seven years' experimenting by the people who invented the first reinforcements for automobile tires.

AUTO OWNERS: See your dealer, he may have MAXOTIRES in stock (for many have), however, if he hasn't—write for our complete free illustrated catalog and prices, express prepaid.

OAKES Beartone

Sounds Thru Radiator

Beartone is in center of cooling fan on motor—in front of motor—under the hood—directly behind the radiator. Other horns are at side of motor and behind fan, which forces back their volume of sound. Touch a button at driver's seat and the Beartone gives any volume or range desired.

for FORD

The Beartone can be interchanged with fan on your Ford by anyone in a jiffy. Replaces "horns," as the self starter has replaced cranking.

The diaphragm is fastened to the central portion of the cooling fan assembly, rotating with it. Inside the fan is a stationary piece which causes the diaphragm to vibrate when brought in contact with the latter. This stationary part is operated by a small lever at back of fan bracket.

BEARTONE GIVES YOU

Safety—Dependable, never-failing warning sounds every time you touch the button at the driver's seat.

VOLUME

Any volume the occasion requires, and any range needed, from a polite whisper to a loud, long-ranged piercing warning.

FAN

You get the best fan, THE OAKES—a *unit* with a horn. Once you put the Oakes Fan on your Ford you will never have to replace it.

LOGICAL

The Beartone Horn Fan is in a logical position, under the hood in front of the motor, not at the side and behind where the pressure decreases the volume.

EFFICIENCY

The Beartone Horn Fan actually increases the efficiency of your motor.

The Beartone pulls more air thru the radiator, keeping it perfectly cool, saving oil consumption, etc.

MECHANICAL

The Beartone is not an electrical horn. It has the same mechanical operation as a high grade motor-driven horn, but with no battery expense, and at a low first cost.

SIMPLE

The Beartone has no complicated mechanism; has no parts to get out of order and give trouble. Requires no adjusting.

TROUBLEPROOF

The Beartone gives you freedom from trouble; never fails to sound. Boys cannot abuse it when car is standing idle.

DOES AWAY WITH:

Motor battery, wires, complicated mechanism, battery expense. No motor to stick in cold weather. No drain on your lights.

Lucrative Dealers' Proposition—
Write At Once.

Non-Skid Wrapped Tread

Mattson Unguaranteed Tires

Experienced Motorists in ever increasing numbers are turning toward

MATTSON
Unguaranteed Tires

They have discovered that they average better value—service and cost considered—than other kinds.

Nobody knows the life of a tire because nobody can foresee the conditions under which they will be used.

Under favorable conditions a tire will last longer—*guaranteed or unguaranteed*—than under unfavorable conditions.

MATTSON Unguaranteed Tire prices have decided thousands of motorists to try them. The Results MATTSON Tires give invariably decide them to keep on using them.

With increased and improved facilities—made necessary by the growing demand—we are entering upon our ninth year in the manufacture of unguaranteed tires.

While we sell only at wholesale we will be glad to tell you where you can get Unguaranteed Tires.

This information will be valuable, for you can save considerable in your tire expense by using MATTSON Unguaranteed Tires—Plain Wrapped or Non-Skid Treads.

Ask your dealer about the other famous MATTSON Rubber Accessories.

- ¶ High Grade Guaranteed red inner tubes.
- ¶ Reliners, Heavy, Medium, Light, Extra.
- ¶ Service tread boots — Lace-on — Hook-on.

300,000 Motors

are now equipped with

Made in All Sizes **LEAK-PROOF** Easily Adjusted

Piston Rings

MADE BY McQUAY-NORRIS MFG. CO.

¶ Think of what this means. One automobile or motor truck in every five of those in use today has LEAK-PROOF Piston Rings in its engine. And—bear this in mind—in every instance these rings were put in by the owners to replace the inefficient piston rings originally installed by the manufacturer. As a result, 300,000 owners are today securing more power, substantial saving in fuel, oil and motor wear and enjoying great relief from carbon trouble.

¶ LEAK-PROOF Piston Rings are designed to secure that perfect gas-tightness within the cylinder without which proper compression of the fuel charge is impossible—and faulty compression must cause reduced power. Further, they prevent the passing of surplus lubricating oil into the combustion chamber, which is responsible for excessive carbon deposit, and they are made to fit so exactly as to eliminate the undue wear that results in loss of all efficiency, frequent replacement expense and regrinding of cylinders.

¶ The great feature of the LEAK-PROOF Piston Ring is its strength and simplicity. It consists of two pieces only, made on the angle-iron principle, each half perfectly concentric and closely fitted around the other, closing up the expansion openings that are left unsealed in the ordinary one-piece ring, without requiring the use of any coupling joint. This is the patented feature of LEAK-PROOF—and marks its individuality. Being a two-piece concentric ring correctly distributed tension on the cylinder walls is secured without the weakness inherent in the multiple section ring.

When your car is overhauled have LEAK-PROOF Piston Rings installed.

Send for FREE Book—"To Have and to Hold Power"

It explains the theory and function of piston rings. It tells about the LEAK-PROOF **Ring** and why every motor should be equipped with them. How it will pay you in fuel economy and prolonged motor life. Write for it.

Effective February 1

Reduction No. 3 On Goodyear Tires

Making Total Reductions 45 Per Cent in Two Years To Give Always the Most for the Money

We are glad again—for the third time in two years—to announce a big reduction on Goodyear tires, effective February 1st.

Goodyear policy on price is to give the utmost in a tire at the lowest possible profit. Our reductions are made to that end, without ever reducing the quality.

That always means, with our matchless output, more for the money than any other maker can give.

As rubber came down our prices came down. As our output multiplied, reducing factory cost, our prices came down with it. In two years our reductions—including the present—have totaled 45 per cent.

Last year we increased our output 26.6 per cent. A few days ago the embargo on rubber was modified so that supplies seem assured. The market price for rubber seems for a time established. Fabric costs less than last year. So under our minimum profit policy, we announce this new reduction.

Only Fair Basis

We consider profit margin on a tire the only fair price basis. We keep that margin just as low as our line allows.

While we do that, Goodyear tires will always undersell any tires that compare with them. That is because we have the largest output. We have a new factory, modernly equipped. And we have world-wide facilities for buying rubber, of our extra grade, at the lowest market price.

For a long, long time most tires have sold much above Goodyear prices. Some have sold one-third higher. A few have sold lower, as some always will, because of less rubber, less quality. But we can and do, under all conditions, give more for the money than any rival tire can offer.

The Best We Know

Goodyear Fortfied Tires offer the best we know. They are built to give you the lowest cost per mile. They minimize tire trouble in five costly ways employed by no other maker. And they are always the same, regardless of price reductions.

Most tires will always sell higher, because of smaller output. Some tires will always sell lower because of lower standards. But we promise you that none will ever give better than Goodyear value.

This policy has made Goodyears the largest-selling tires in the world. It will make them more so as more men find them out.

Ask your Goodyear dealer for our new price on the size you buy.

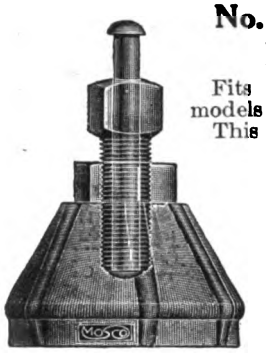
FORD FITTINGS



No. 2 WHEEL PULLER
for the Ford Car

This model has our new loose plunger feature as used in our No. 3 model. It also has an adjusting screw to provide for the variation in hub threads often found in the Ford car. No stripping of threads is possible with this puller. Made of semi-steel casting with carbon steel fittings.

Price $1.00

Patented March 24, 1914. Dec. 15, 1914.

No. 3 WHEEL PULLER
For Overland Cars

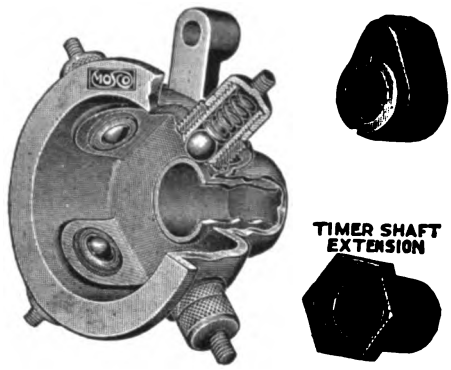
Fits all Overland 30 and 35 H. P. models of 1913, 1914 and 1915.

This puller has an absolutely new feature in the loose plunger which extends through the center of the screw, affording a means of starting off a wheel which is stuck or "frozen" to the axle. A sharp blow with a hammer against the end of plunger is a wonderful help.

$1.25 Each

Patented March 24, 1914. Dec. 15, 1914.

MOSCO GASOLENE GAUGE
For the Ford Car



Dial cover ONLY removed for filling. This permits filling of tank without removing the device.

This is undoubtedly the best Gauge ever made for the Ford car as it has a number of advantages not found in others. There is no attaching work. The device is simply screwed into the tank in place of the present filler cap. The indicator automatically engages in correct position as the cap is screwed into place. The device occupies even less vertical space than the present filler cap. No other Gauge has so large an opening available for filling. This Gauge cannot be injured by the introduction of filling funnels or the nozzles used at filling stations. It can be used in the dark by feeling the location of the pointer on the dial.

PRICE $1.50

The New BEMUS TIMER
FORD CAR TYPE

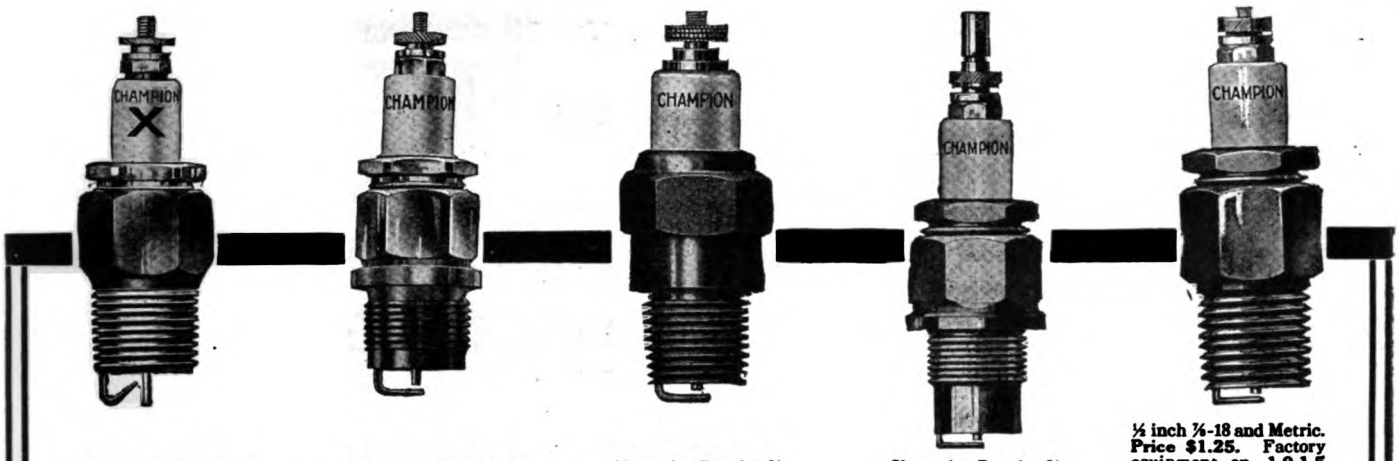
BEMUS BALL CONTACT TIMER

Every practical man who knows the Ford car recognizes the fact that this short stroke, high-speed engine requires a Timer capable of rapid, snappy action in the making of contacts and yet having durability sufficient for thousands of miles of running without loss of efficiency.

THE BEMUS IS BEST FOR THE FORD
BECAUSE

CONTACT is made by a hardened tool-steel brush engaging steel balls with short, glancing impacts, both the brush and the balls turning each time so that fresh contact surfaces are continually engaged.

MOUNTING is direct on the time shaft by means of an extension piece. This brings each of the balls equi-distant from the brush. Result—absolute precision of timing.



STARTING is facilitated in cold weather because these contacts do not hold a body of oil to prevent passage of current.

DURABILITY of unlimited extent is due to a construction which eliminates all wear of the insulation. The roller brush is reversible, and when worn on both sides may be replaced by the user together with new contact balls at an expense of a few cents.

The "Ford" Plug—Special ¼ inch with Champion.
Plug adopted by the Ford Motor Company as standard equipment on Ford cars since 1911—Price 75c.

Champion Regular ½ inch. Price $1. Factory equipment on all Studebaker Cars. Factory equipment on all 1913 and 1914 Overland Cars. Nickel finish.

Champion Regular ⅞-18. Price $1. Factory equipment on Maxwell Cars. Nickel Finish.

Champion Regular ⅞-18 long. Price $1. Specially made for Buick Cars. Has Buick Terminal, long shell, conical porcelain. Nickel finish.

½ inch ⅞-18 and Metric. Price $1.25. Factory equipment on 1915 Overlands. Specially made for high power and racing cars. Extra heavy material throughout. Absolutely compression tight. Gun Metal finish.

Why Champion Spark Plugs Dominate the Field

For the last five years, the demand for Champion Spark Plugs has always far exceeded the supply.

Every year, the output has fallen short of the actual demand.

Why?

Because the manufacturers of Champion Plugs would not sacrifice quality to quantity. That they have chosen the right policy is evidenced by the fact that their output now exceeds over 26,000 plugs per day, and their factory has grown, from a small beginning, to be, by far, the largest and most perfectly equipped spark plug plant in the world.

Champion Spark Plugs stand for quality and efficiency. Their reputation for quality has been built and maintained by the use of not only the best materials, workmanship and superior design, but by the unsurpassed manufacturing facilities, which have enabled this product to be placed on the market in a uniformly perfected state.

Over three-quarters—seventy-five per cent of all the cars built in America are equipped at the factories with Champion Spark Plugs.

The engineers of these automobile manufacturers have found that Champions are the best adapted to their motors, and insure the greatest amount of efficiency and durability.

Ford, Overland, Studebaker, Maxwell, Metz and over fifty other famous cars go to their owners when new supplied with Champion Spark Plugs. This, alone, should be sufficient reason for the owners of any of these cars to see that all replacements are made with Champion Plugs.

There is a Champion Spark Plug made for every automobile, motor truck, motor boat, motorcycle, aeroplane and stationary motor.

See your dealer.

STRONGEST GUARANTEE EVER MADE:—Complete satisfaction to user, or free replacement, repairs, or your money back.

SOME REPRESENTATIVE ATWATER KENT-EQUIPPED CARS

Straws from the Show

AT the Chicago Automobile Show seventy-seven cars were exhibited.

Of these 77 cars, 34 were magneto equipped, and 43 depended solely on battery ignition. While none of these battery-equipped cars had any other form of ignition, a considerable number of the magneto-equipped cars had auxiliary battery ignition.

Of the 43 cars using battery ignition exclusively, 20 used the Atwater Kent Ignition System. The others were divided between four different makes.

In a word, one-quarter of all the cars at the Show were exclusively Atwater Kent-Equipped.

The reason for its phenomenal growth in popularity is that Atwater Kent Ignition *rounds out the engine performance* at points where other systems leave it weak.

With Atwater Kent Ignition the engine *starts* much easier, *idles* more slowly and quietly, *pulls* stronger at low speeds, and *accelerates faster* than with the ordinary magneto equipment.

Constant spark heat at all speeds, accurate synchronism, correct automatic advance are the birthright of any engine. Atwater Kent Ignition gives them all with unfailing dependability. Its principle is basic.

Atwater Kent Mfg. Works 4933 STENTON AVENUE PHILADELPHIA, PA.

Seven Killed for Seven Cents

An automobile manufacturer was making out the specifications for the coming year. It came to a choice of brake lining—Thermoid or some other.

Thermoid was conceded to be superior, but it cost seven cents more per car than a competing brake lining.

The cheap lining was the usual kind, with friction surfaces but friction-shy inside—a loosely woven fabric that could not possibly remain efficient beyond a limited period.

At least one of the manufacturer's cars was bought by a novice. He drove his car poorly—used his brakes constantly—took little care of it—knew nothing about its mechanism. He took the manufacturer's word that the car was mechanically perfect.

Without going into details, this owner met with a terrible accident in which seven people were killed. Examination demonstrated that the brake lining had become useless and at a critical instant *the brakes failed.*

If Thermoid had been used, the brakes would not have failed—could not have failed.

The manufacturer had sacrificed seven lives for seven cents.

Inasmuch as he makes many thousand cars a year, how many more frightful accidents may be charged to the false economy of his purchasing department?

When a manufacturer deliberately cheapens his car to the danger point, he is morally responsible for every accident that results from that sacrifice of essential quality.

It seems inconceivable that a manufacturer will, for seven cents, take chances with so vital a safeguard as the brakes of an automobile.

Yet it is done constantly.

A manufacturer cannot plead ignorance. His engineering department can prove in a few minutes the great superiority of Thermoid over any other brake lining. His engineers *know* and *concede* the superiority of Thermoid Brake Lining. His only possible reason for using a poorer brake lining is to save seven cents on every car.

Is it worth it?

Patronize the Dealer Who Gives you What you Ask For.

The store selling standard products is the store that is sought by the careful buyer. Such purchasers know what they want, and it is a waste of time for dealers to "talk" or attempt to push the sale of "Just as Good." Remember, when a dealer offers you an imitation article he makes a bigger profit, otherwise he would not handle it. What do you get if you handle his "Just as Good"? Certainly not the quality for which you pay. The name of a well-known maker on a product is the best assurance you have of the uniform quality of the product. Your salvation from injury or deception is to ask for products by name of Maker or Trademark Brand and the determination to demand that the dealer supply the identical product asked for. Good-service dealers will not attempt to offer you substitutes, because they appreciate your patronage and realize that the growth of their business depends upon giving customers what they ask for.

Insist on [redacted] Ford Specialties. *"Get What You Ask For."*

DEALERS and JOBBERS: Write for our discounts, they are right and the [redacted] goods will make friends for you.

1/3 Of Your GASOLINE SAVED BY THE

Economy Gasoline Improver

OR SUPER-CARBURETOR

Cold water will not give off steam, and the best carburetor on earth will not give off real vapor without the assistance of heat, at any time of the year. **Boiling Gasoline** is used at the big races in the middle of the summer.

The Economy Gasoline Improver uses waste heat from the surface of the exhaust pipe to heat the gasoline in the gasoline pipe before it enters the carburetor, greatly increasing the power, improving the running of the engine, decreasing the deposit of carbon and permitting a saving of **One-Third of Your Gasoline. YOU CAN SEE IT SAVE.**

We guarantee that with the **Economy Gasoline Improver** on your car you can turn off the flow of gasoline to the carburetor ⅓ after the engine is warmed up, and still get full efficiency.

PRICE $2.35 A Special Offer will be made once to each new dealer. Write for it.

Order through your dealer or direct from us. We ship by insured mail same day order is received. **We pay the postage.**

Every Ford Owner A Possible Customer

Your market for Livingston Radiators and Livingston Sloping Hoods is limited only by the number of Ford cars in your territory.

We specialize in Honeycomb Radiators and Sloping Hoods for Ford cars.

Owing to a large demand and output, we have cut the cost of manufacturing to the minimum.

Livingston Radiators have been recognized for years by high class motor car manufacturers as superior in construction to all others.

Livingston Radiators are the most efficient for the following reasons:

1st. All the radiating surfaces are in direct contact with the circulating water, insuring direct radiation.

2nd. The water in the Livingston radiator travels around three sides of the square, in vertical and horizontal runs, making the length of the tube twice its height, thereby keeping the circulating water in contact with the air twice the length of time, giving increased efficiency with less weight.

POINTED FRONT.—The Livingston Pointed Front radiator will greatly improve the appearance of a Ford car by giving it long lines, and adding to its style, beauty and individuality.

LIVINGSTON SLOPING HOODS give the long stream line effect so much admired in cars of higher cost. They can be used in conjunction with any radiator built for Ford cars. Sides are ventilated to permit of additional cooling, by allowing the heat generated from the motor to escape from under the hood.

All Livingston products are sold under a "30-day guarantee." If not satisfactory, they can be returned to us any time within 30 days (transportation charges prepaid), and the money will be cheerfully refunded.

All Livingston products are absolutely interchangeable with radiators and hoods that are standard on the Ford job.

DEALERS—Hundreds of dealers are making added profits by selling Livingston Products.

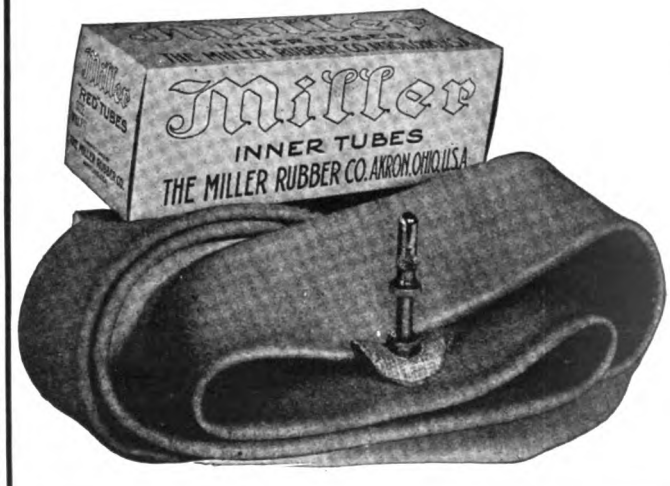
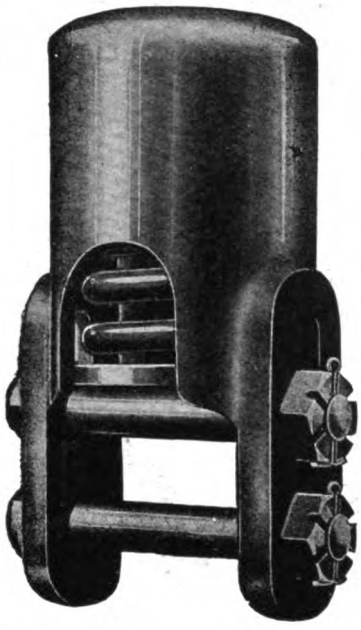
What's the Answer to the Tube Question?

Miller
Red Tubes



But they can't give You that feeling of Security and Freedom from Tube Troubles unless they're in Your Casings.

Miller Red Inner Tubes are made of pure gum, built heavy and strong, yet so exceptionally elastic that they do not lose their shape. Double reinforcement at the valve, by means of a large, strong base, gives additional protection where wear is most severe.



Miller "Hook Hold" Boots hold firmly after tire is inflated. Pluggum saves tire bills by giving a quick, permanent repair (without vulcanization), to cuts in casings. Both are built up to the Miller Standard of Quality.

The Miller Dealer has the size tube you need and a full line of tire accessories.

REPAIRING AUTOMOBILE TIRES

Sounds like a lot of money—IT IS—A WHOLE LOT of MONEY to be earning CLEAR every month—yet it's what hundreds of men we have established in the Automobile Tire Repair Business are making. You let down the DRAWBRIDGE for SUCCESS to enter into your career by getting into business for yourself. The business for you is one where the investment is small—the returns quick and for cash—where the margin of profit is large—the demand for your PRODUCT or SERVICE constant and ever on the increase.

A HAYWOOD TIRE REPAIR EQUIPMENT

answers to all of these requirements of Old Dame Fortune—the certainty of success in this business is as sure as anything in this world can be—Each year adds thousands of new Automobile Owners—they need YOU to keep their tires in service.

HERE IS YOUR OPPORTUNITY!

Be first to enter this new, big paying business in your town. Open your pockets. Let the dollars pour in. Act quick. Every auto sold means more tires to mend. Automobile business is growing fast—enormous field for tire repairing. Punctures and blowouts are common. Tires need retreading and vulcanizing. Something going wrong all the time. Thousands forced to buy new tires because they can't get old ones fixed. Think of the old bicycle days—repair shops on every corner—all making money—busy day and night. Autos make same proposition over again—only ten times bigger and better. Users of Haywood Tire Repair Plants are making big money. Johnson, Tex., writes: **"I have made as high as $18 in a day."** Another man who bought a plant September, 1911, writes he has **cleared over $3000.00.** That's going some! Operate a plant as a side line in connection with auto business—garage, or as an independent business. Find neighborhood where there's a bunch of autos—get all the steady business besides transient work. Experience unnecessary. You learn quick. Simply follow directions—practice a few days on a couple of old tires and you'll be ready to coin money. Business comes fast and easy.

THIS MAN IS MAKING MONEY

Repair Tires at Home!

Young men and boys! repair father's tires—get money he pays garage man. Get the neighbor's work. Make money to attend college or to start a garage and repair business. **Auto owners**—repair your own tires—save money—pay for your outfit in short time. We have outfits for home use. Anyhow, investigate. Send today for catalogue. See the wonderful possibilities in this marvelous field. Learn of the enormous money-making opportunities in this fascinating new business.

The New Money-Making Business—Start Now.

THE CANVAS TREAD TIRE

With its many layers made of rubber and rubberized canvas impregnated with tread stock in such a way that each layer is woven to the other with rubber and afterwards vulcanized, which makes a stronger and more serviceable tread than the all-rubber tread heretofore used. These layers will not separate, peel off, crack, split, or chunks come out, like the all-rubber tread by the constant vibration. All of these layers are non-skid, but yet a smooth tread, and each layer as they wear off becomes a non-skid and so on until the entire tread is worn out. It takes more than 1,500 miles to wear off one layer. Count the number of non-skid layers and you will see that this tread is good for more than 10,000 miles. It is a tougher tread and more serviceable than heretofore used in other makes of tires. It is the only non-skip tire all the way through ever made, no chains are necessary. It is what is known as a fast tire and takes less engine power and 25 per cent less gasoline. It is free from punctures, stone bruises and never gives any trouble. Try one of these tires with any other tire, which will quickly convince anyone. We only use the most expensive material that goes to make up a tire. If you paid us a $1,000 for a tire, we could not make a better one, because better material is not made. This tire is backed up by the highest percentage of mileage guarantee.

Send for booklet telling many other features and agent's proposition.

AUTOMOBILE LUBRICATION.

More About Testing—High Viscosity and Its Relation to Friction.

BY SYDNEY F. WALKER, M. E.

While on the subject of testing, it may be as well to refer to testing machines that are on the market. Practically all of them are based upon the imitation, as closely as can be arranged, of the conditions ruling between the surfaces that are to be lubricated. It is the reproduction of the exact conditions ruling in practice that is always so difficult in the testing laboratory, and that is one reason why laboratory tests are so often received with suspicion. It is so very difficult to get all the factors into the equation. In one form of testing machine, two surfaces are kept running over each other. It is merely a variation in detail, for one surface to be stationary and the other moving; or for both to be moving. A given oil is fed to the lower surface, or at any rate caused to pass between the surfaces, at a given rate. With some tests, a given quantity of oil is fed to the space between the two surfaces, and the indications are watched. Arrangements are usually made, enabling heat to be applied. Up to the temperature of superheated steam, say 600°F. or 650°F., there is no difficulty about this; and so far as is known at present, those would be higher temperatures than the lubricants would be exposed to. It has been estimated by one engineer who has given very great attention to the subject, that the temperature of the film of

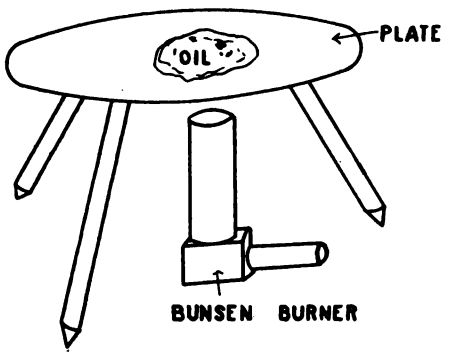

Fig. 14—Diagrammatic sketch of suggested method of testing a lubricant by heat. A measured quantity of the lubricant is to be allowed to fall on the upper side of the plate, and the under side is to be heated by a Bunsen burner.

oil between the piston rings and the cylinder walls, in an internal combustion engine, does not exceed 300°F.; and is usually much less than that.

In the testing machines referred to above, care is taken that the oil can flow to every part of the surfaces that are rubbing together. It is also arranged that the speed at which the surfaces rub together, can be varied within wide limits, say from 50 revolutions up to 3,000 revolutions per minute. Pencils working over revolving drums carrying paper, divided up into squares, in the usual way, trace out the pressure between the two surfaces in contact, and the temperature of the surfaces. When only a certain small quantity of the oil to be tested is placed between the rubbing surfaces, the temperature and friction rise very slowly at first, and then apparently, according to the makers of the machine, it rises very rapidly. They claim to be able to discover the comparative values of different oils, at

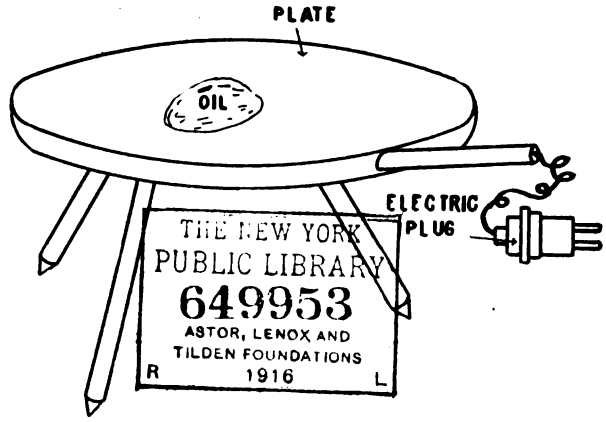

Fig. 15—Diagrammatic sketch of an electrically heated plate for testing oils. The arrangement is similar to that for heating with a Bunsen burner, but the heat is applied by an electric current flowing in a heating element, buried under the plate.

different speeds, and at different temperatures; by the time that elapses before the breakdown occurs. Fig. 16, shows a curve that illustrates this. It will be seen that in the case shown, the temperature rises very slowly, up to a critical figure represented by about 46,000 revolutions; and then it rises very suddenly. Similarly in Fig. 17, which is the record of the friction, the resistance set up to motion between the two surfaces; it will be noticed that it rises very quickly at first, before the oil has time to penetrate between the discs; then it falls to a low figure and rises very slowly, by steps, until the same critical time as in the first figure, when it rises very quickly.

The idea underlying this is, that a given lubricant has a certain staying power, so to speak; that a given quantity tested in this particular machine will break down after say 46,000 revolutions, and the surfaces in contact, if allowed to continue to rub over each other, would very soon seize. Another set of curves is shown in Figs. 18 and 19, where it will be seen that the rise was very gradual, until 27,000 revolutions had been made, when the rise in temperature became more rapid; and in the case of the frictional resistance, the sharp rise occurred at about 30,000 revolutions. It will be seen that the rise in the pressure is very sudden after the critical time.

These tests are after all only comparative; and as in so many other cases, it is only by long experience of different oils, passed through the machine, under exactly the same conditions, the oils being

Digitized by Google

followed to their actual work in engines, that really accurate information can be obtained. What the present writer wishes to bring out is that in every repair shop, and in every manufactory, it should be quite possible to rig up apparatus of a simple character, to which oils offered for lubrication might be submitted; and from which a good general knowledge of what the oil is likely to do under working conditions would be obtained. Of course each oil should be followed; and a record kept of the tests made upon it. To a man who is constantly working with the oils, passing them continuously through his hands, the record will be very efficiently kept in his own head. He will be able to tell very quickly, when he exposes a small quantity upon the heated plate, whether it is worth while taking further tests.

It should not be a difficult matter again to rig up a pair of discs revolving one upon the other to which a measured quantity of oil could be supplied, the system being set in motion say by a small electric motor, and either the time taken before heat appears or the motor set to come to rest after spinning the apparatus for a certain time. Fig. 20 is a rough diagram of the suggested arrangement. As is well known, automatically controlled electrical apparatus are very common indeed, particularly in America. Some of the apparatus that have been worked out in America, are almost human in the way in which they operate, and the writer's idea is that it would be quite simple to arrange for the motor to make a certain number of revolutions, and then to stop.

Viscosity.

The term "viscosity" is very difficult to define. It is perhaps best described as the opposite to fluidity. The more viscous a fluid is, the less freely does it flow. Pure water for instance flows freely, and at

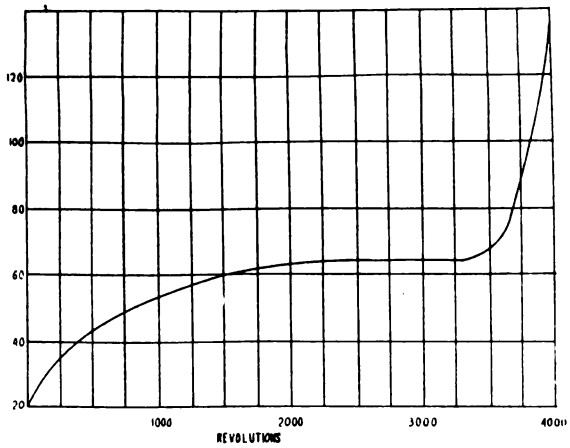

Fig. 16—Curve showing increase of temperature between two surfaces in a testing machine, after different total numbers of revolutions. The curve illustrates the breakdown of the lubricant.

the other end of the scale—pitch—though it is looked upon as a solid, does flow when exposed to pressure, though at a very slow rate. Between these two extremes are a very wide range of fluids.

The viscosity has an important bearing upon the efficiency of a lubricant. High viscosity means a certain likeness to treacle, a tendency to hang about the bearings, and the surfaces to be lubricated; and a highly viscous lubricant will set up friction by itself. For heavy slow running machinery, solid fats, which are of course very viscous, are employed; but it is not the fat in the solid state which performs the office of lubricant, it is only when the heat that has been liberated in the bearing, or between the surfaces to be lubricated, has caused a certain quantity of the solid fat to be formed into a liquid that it performs its office. The surfaces requiring lubrication in a motor car, with the exception of some of the gear wheels, move over each other at high speeds, and therefore a highly viscous fluid would be quite out of place. On the other hand, a certain amount of viscosity is of great value in the lubrication of the cylinder.

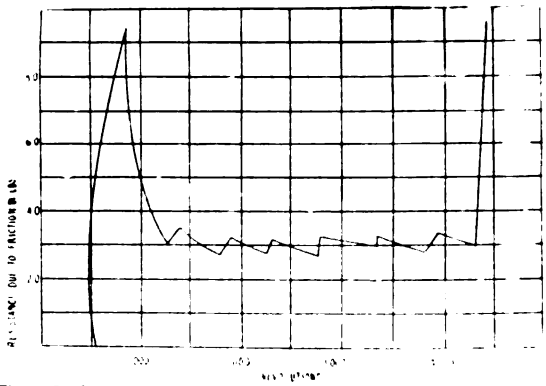

Fig. 17—Curve showing the variation in frictional resistance between two surfaces in a testing machine, after varying total numbers of revolutions. As will be seen, the frictional resistance rises very much at first, then falls to a certain figure at which it is nearly constant, till a certain number of revolutions have taken place, when it rises very rapidly. This also marks the breakdown of the lubricant.

Vertically placed cylinders, as all motor cars are now fitted with, are not subject to the same amount of wear as horizontally fixed cylinders. One great trouble with horizontal cylinders is the weight of the piston bearing upon the lower half of the cylinder wall, gradually wears it away, and wears its own piston rings away. There is nothing like this in the vertical cylinder, but there is always the possibility of some inequality, either in the machining, or more likely in the material, of which the cylinder, or the piston rings are composed. A little extra hardness, or a little extra softness, either in some part of the cylinder walls or in some part of one or more of the piston rings, will give rise to wear at those points; and the wear will unfortunately tend to increase. Where this occurs, a comparatively thick, viscous lubricant is of great service in filling up the gap.

It follows of course that if wear occurs, either in the piston rings, or in the cylinder walls, there will be a leakage of the hot gases past the piston, with the result that the efficiency of the engine will be reduced, the quantity of gasoline used per mile will be increased, and the lubricant in the crank chamber will be subject to the deleterious effect produced by the hot gases. Even the leakage past the piston of a small quantity of the hot gases into the crank chamber, occurring as it does say 2,000 times a minute, will have a seriously deteriorating effect upon the liquid lubricant in the crank chamber. The crank chamber itself will necessarily be hotter than it otherwise would be, the hot gases will act chemically upon the lubricant, carbon will probably be deposited, and there will be other troubles. It has been shown therefore by practical experience, that too thin an oil in the crank chamber, and for lubri-

Digitized by Google

cating the piston is not good, and too thick, too viscous a lubricant would also be out of place. It is the happy means apparently which gives the best results, and this can only be found by experience. But when once an oil has been found, whose viscosity answers with a particular engine, under practically all conditions of service; it is not difficult to test the viscosity of other oils that are submitted for purchase.

How the Viscosity is Tested.

It should be mentioned, before describing the apparatus employed, that viscosity varies very much with the temperature. As the temperature rises, the viscosity lowers, and with higher and higher temperatures, the viscosity is lowered more and more rapidly. In testing the viscosity of any oil, therefore, it is important that the conditions of temperature should be the same. The method of testing is by measuring the rate at which the oil under test flows, and this is accomplished by filling a vessel of known volume, maintaining the temperature of the oil in the vessel at a given standard figure, and allowing the oil to flow out through a small hole in the bottom of the vessel, the hole also being of standard size. The standard quantity is usually 50 cubic centimeters (say 7¾ cubic inches), and rape oil, maintained at a temperature of 60° F., is the standard, with which other oils are compared. The 50 cubic centimeters of rape oil flows out through the Redwood viscometer, which is shown diagrammatically in Fig. 21, in 535 seconds. Oils that are more fluid than rape, which are less viscous, flow out in a smaller time, while more viscous oils take longer. The writer suggests that if a viscometer is employed to test oils, they should not only be tested at the standard temperature of

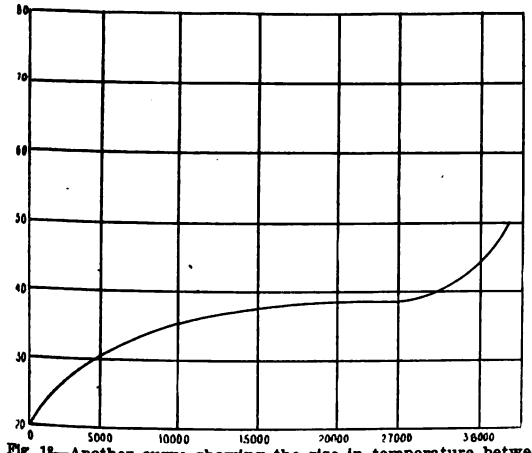

Fig. 18—Another curve showing the rise in temperature between two metal surfaces in a testing machine.

60°, but at increasing temperatures up to say 300° F. at least. This of course demands special apparatus, and special means of heating the vessel, and of maintaining it at the given temperatures during the whole of the test. He suggests this, because it has been found that the viscosity of different oils varies as their temperature is raised. With some oils the viscosity falls very much more rapidly than with the others. The important point to know is, of course, how the oil will behave, when at the temperature to which it will be exposed.

In the Redwood, and practically all viscometers, there is a vessel that will contain the measured quantity, 50 cubic centimeters, of the oil to be tested, when the oil is at a certain level in the vessel. The oil vessel is carried inside another vessel through which hot water, or any other liquid can be caused to flow, so that the temperature of the oil whose viscosity is to be measured, can be maintained constant during the whole of the test. In the bottom of the vessel containing the oil, is the small hole, closed till the test commences by some simple valve

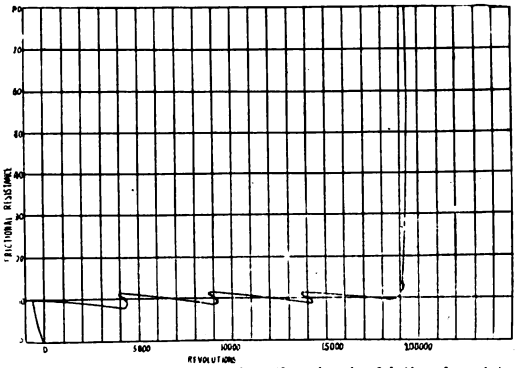

Fig. 19—Another curve showing the rise in frictional resistance between two metal surfaces in a testing machine.

that can be opened from outside, such as a ball attached to a thin rod. Underneath the viscometer a flask is usually placed, holding exactly the same quantity of the oil as the oil vessel. Arrangements are made for thermometers to be inserted in the oil vessel, and in the heating baths. The oil to be tested is heated to 60° F. before placing it in the viscometer.

A rough and ready method of testing the viscosity of oils is, by allowing a single drop of the oil to fall upon an inclined plane, and measuring the time required for it to run down over a certain measured distance. Of course there are a number of what mathematicians call independent variables in this matter; and in order that the test should be of any value, care must be taken to eliminate them as far as possible. The board employed for instance should always be the same, and it should be in exactly the same condition; and at exactly the same inclination. Further, for the test at ordinary temperatures, care should be taken that the temperature of the oil itself, and of the atmosphere in the neighborhood of the test board, and of the board itself should be the same. A comparatively viscous oil for instance, if tested on a hot day in summer, in nearly every part of America, would give a very different result, from the same oil, tested at the same place, say in the depth of winter. Again a very different result would be obtained from the same oil, at the same temperatures, with the board having rather a sharp inclination with the horizontal, than with one having a very slight inclination. Further, if the board is rough or dirty, it is quite evident that the drop of oil would not be able to run down it at the same rate as if it was smooth. Further, if means had been taken to reduce the temperature of the oil in the bottle, or the can, from which the test drop is being taken, to say 60° F. or 70° F.; if the board is exposed to the sun's rays, even in winter, or if it is in a warm part of the works, the drop of oil will lose a considerable portion of its viscosity. And perhaps more difficult than all is the measurement of the drop itself. The day has gone by when doc-

Digitized by Google

tors and chemists used to send out medicine, with instructions that so many drops were to be taken, say on a piece of sugar at certain times. Even now, however, a good many patent medicines are sold, in which the instructions for taking are in that form. In the days when drugs of that kind were measured in drops, chemists, at any rate, and assistants, acquired a considerable amount of skill in measuring the drop.

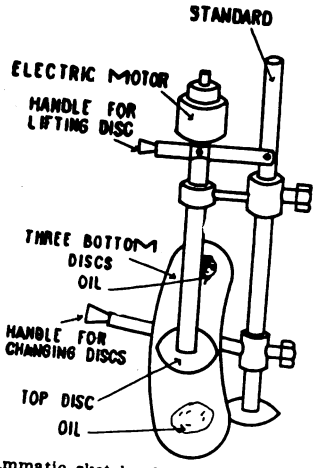

Fig. 20—Diagrammatic sketch of a suggested electrically driven oil testing apparatus. There are two discs, one above the other, the top one moving over the bottom one. The top one is driven by the electric motor shown.

A little examination of the question will show that the size of the drop will depend upon a good many things; upon the form of the lip of the bottle, upon the bottle itself, upon the inclination at which it is held, upon the quantity of oil in the bottle, and so on. But again, for rough and ready tests, it is not very difficult to reduce a large number of these difficulties to very low terms. It would not be difficult for instance to have a small bottle made with a special form of lip and holding a certain definite quantity, and to provide a sort of cradle, in which the bottle would be held, with means to tip it at a certain definite angle. The cradle and bottle might be fixed over the board.

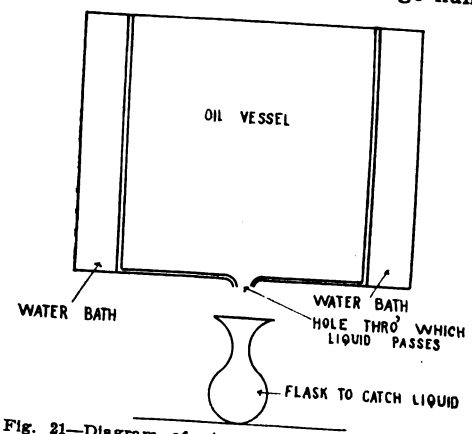

Fig. 21—Diagram of viscometer, Redwood pattern.

Given a board whose surface is always of a certain smoothness, whose surface is always perfectly clean, always at the same angle, always at a certain given temperature or nearly so, any man who is constantly testing oils would be able to form a very good idea of the viscosity of different samples of oil passing through his hands, by filling the test bottle, allowing a drop to fall from it on to the board, and watching the time it took to run down. With the writer's own experience in making tests with different apparatus, his view would be, that after a little time a man who was continually making these tests would know almost as soon as the drop of oil had fallen whether it was of the viscosity required or not.

(To be continued.)

THE REPAIR SHOP.

The Question of Replaced Parts or Making the Old One Answer.

BY JAMES F. HOBART, M. E.

Which shall the garage man do, repair the old broken part or send for a new one from the factory? Which is the best for the car owner, the garage man and for all concerned? There even is an ethical side of the question which should be considered. But the question is a most difficult one and cannot be answered the same for all cars, for all times, and for all shops.

When a man has an accident and smashes up his car within a short distance of the factory where the car was made, it would be worse than foolish for the repair man to make all the parts which are broken. But were the car to be used up in the mountains of Montana, thousands of miles from its shop in the East, with freight amounting to 50 per cent. of the cost price at factory, then it is time to consider the making of parts instead of sending to the factory for them.

To come right down to bare treads, it is the duty of each and every repair man to decide impartially what parts he will make, and which he will order from the factory. It is now a growing tendency, along populous routes, for certain garages to cater to certain makes of cars. To concentrate, so to speak, all their energy and all their enterprise, upon one or two makes of cars; to carry in stock as many parts of that car as possible, and to make and maintain tools and jigs for making parts of those cars to the exclusion of others. In remote locations of course this cannot be done, and in such places "repairs" are the rule, while "renewals" become the exceptions.

The garage man must therefore decide for himself as to whether he will—make or order. But let him, once for all, do so with due regard to honesty and fairness. Let him not decide to repair because he can make more money thereby, to the despair of the car owner. Let the garage man decide in all fairness to the car owner, and discuss the matter with him, stating prices and time for obtaining new parts.

Of course when time is limited then repairs go and the owner expects to pay a little more for the repairs in view of the time saved thereby. But here is where shop ethics come in. It is the duty of the repair man who desires to make new parts, to make and maintain the required jigs; tools, attachments and fixtures whereby parts may be manufactured at a reasonable cost, considerably below what it would cost to "make" a single part in a shop not fitted for such work.

To put the matter in another shape, the repair

Digitized by Google

man should put a certain portion of time and material into make up jigs for turning out repair parts. Instead of charging the customer, as many repair shops do, with "time and material" for the jigs, tools and fixtures, the repair man should charge up a certain portion of the cost thereof to "tools and jigs" and thus add to the shop equipment in a manner fair to himself and to his customer.

No sane repair man would think of charging the cost of an acetylene welding apparatus to the first customer who brought in a water jacket to be repaired, but wouldn't you think of charging the entire cost of a jig for machining a new cylinder, should you make up such a jig, even with the hope of machining many more cylinders upon the same jig? It would be human nature to do so, but it is not justice to you or to your customer. Too much of that kind of work is done, but it is not honest or ethical. Put a portion of tool and jig cost at least into the shop equipment column, and in a short time you will be so equipped with tools and jigs that you can make "repairs" as cheap or even cheaper than you can obtain "renewals" from the home factory or the nearest distributing center.

You can't afford to make engine parts in a garage unless you are willing to invest considerable money in jigs and fixtures, as noted in a preceding paragraph. And furthermore, you can't put all these necessary things in a small shop; therefore, if you decide to go into making repairs then you must branch out, put in a large shop equipment and take means to get business enough to pay for so doing.

A Manufacturing Business.

The making of automobile repair parts is going to run you right into a small manufacturing business—that's just what it will amount to. To be sure, you can't turn out a crankshaft quite as cheaply or as quickly as in lots of 100 or 500, but you should have the tools and jigs all ready if you set out to do that kind of work on crankshafts no matter in what sized lots they come along.

And as matters go on, you will find yourself up against several vital and interesting problems which must be worked out if you stay in business. You will find that your shop has an "overhead" and that overhead won't be a loft or an attic, either. It will be a steady outgo for tools and jigs, and for interest on the amount invested, also for insurance, rent, taxes and depreciation. In short, you will find your shop so covered with fixed charges which go on all the time, whether you do any business or not, that you are obliged to get out and hustle for business in order to live to hustle.

And it is this sort of thing which will drive you into specializing in the repairs for one or two makes of car. You find that you cannot afford to carry castings and unmachined parts for all cars, but that you can do so for one or two cars, and make a nice profit, if you can only get business enough on those few makes of car. And right here you become a "repair specialist" and have a nice business started, when along comes another chap and opens a shop right besides yours and starts the automobile repair business also. But don't get discouraged at this. Go right ahead with your specialties and let the newcomer take the rest of the work which comes along. If he is wise, he will soon do as you did and settle down to the repair of one or two makes of car other than those you attend to.

If you both attend to business, you will find that you are doing even better than before the newcomer came along, and he is doing well also. And right here is a fine chance for you to increase your income and do a still greater business than before. It is in this way: Buy out your neighbor, or go into partnership with him. There are two sets of overhead expenses which can be lessened a bit by having the two shops under one management. In the buying of material, the cost of so doing, as far as clerical expense is concerned, may be cut in half, and in the obtaining of new business the cost may be lessened by one-half also for the men who obtain business, for you can handle the four makes of car as well as the two makes which each shop now caters to.

And in the matter of shop tools and equipment —there is a good deal which must be common to both places, which can be dispensed with when both are under one management. And some of the workmen will be able to do similar work for both shops without being too busy with either, thus making a good saving in that direction. In fact, the consolidation of the two shops yields to their owners most of the benefits, though on a somewhat smaller scale, as those derived from the merging of two manufacturing businesses into a single management —a young "trust" in fact. Now I am not by any means advocating the forming of a repair trust in automobiles, but I am merely pointing out the benefits to be derived from going into the repair business in a businesslike way.

You want to go into the automobile repair business as though you were going to make a business of it. In fact, go to the work so you can manufacture repairs. You don't want to fool yourself that you can put up a 10x16 foot shack with a portable forge and a drilling machine and then set up as a first class automobile repair shop. With such an outfit you can make repairs, but you can't manufacture them, and that is where the profit comes from in the automobile repair business—from manufacturing repairs—not from "making" them.

Bear this in mind when you start the automobile repair shop and plan things right through so you can do the business profitably when you get it. And when you are fixed to manufacture repairs, and have the know-how to do so, there is not the least doubt but what you will get the business—if you go after it.

Small Shop Profitable—Sometimes.

Many a small shop has proved profitable; many another small shop has failed and it went under so quickly that nobody even heard the splash. I know of a very large and successful repair garage which was started with no tools other than a breast drill, and the other small tools usually found in a machinist's tool box. The man who started this shop had the know-how and was willing to work and work hard. He did, and now he has a fine shop, manufactures repairs and has also manufactured several good automobiles. No, he didn't "make" them—they were "manufactured" in the truest sense of the word. He could turn out other cars to advantage if the shop had time, but it is so busy with profitable repairs that the owner does not care to go into car manufacturing to any extent save as a means for filling any gaps which may come along during dull times.

This shop is not a small one by any means. It got over that several years ago, and now covers

Digitized by Google

considerable territory, and even has a little foundry. One of those affairs built into a steel cylinder, placed horizontally, and fed with gas. After the metal has melted, either iron or brass, you turn the melter sidewise on its trunnions and pour out the molten metal almost the same as you would from a big foundry ladle with geared hand wheel attached. You can operate one of these melters with artificial, natural or "producer" gas, the latter kind being easily made from coal and from the cheapest kind of coal at that.

With a producer, you can make gas to run a cupola, also for operating your own and your neighbor's gas engine. You can also profitably attach another gas engine to the producer and make electric light for your own and neighbors' shops, residences and stores. In fact, you can soon work up a nice little business in that direction in connection with your "manufacturing garage."

Furthermore, when you get the home shop well started on repairs for a couple of good standard machines, then try the matter of starting small shops in adjacent places a few miles away. You can start very small places and supply them with parts made in your central shop, which is only a short distance away by automobile or by parcels post and telephone. Work up a half dozen places in that way, and you can have your specialty repairs started toward each or any of those subsidiary shops before the damaged automobile has fairly been taken down for repair.

Try this scheme, you man who is "looking for a good thing," and I don't believe you will find a better one if you look, and keep looking from January 1st to December 31st. But remember one thing: You can't make money by starting a repair garage, manufacturing your own repairs, and then expect the business to run itself and make money for you. It will require the hardest kind of continual work to pull off a stunt of this kind, and it will require a lot of experience and know-how as well. But if you have the latter, the former will come along every day of the year and you can have a nice business for the work of building it up.

Rosin Radiator Repairs.

On page 35 of the January issue there is a little paragraph to the effect that leaks in pipes or tanks may be temporarily repaired by pouring melted rosin over the crack, reinforcing the rosin if necessary with a bit of leather placed in, under or over the rosin, as required by conditions. I have used this method for a long time, and have worked out several modifications of it which seem to improve the original proposition very much. As gasoline soon cuts its way through rosin, it is better to fill the crack with common yellow laundry soap before applying the rosin. A slight thickness of soap may also be spread over the crack, and allowed to extend a short distance to either side. This will prevent the gasoline from eating its way through the rosin, which may be quickly and nicely put in place by means of an ordinary soldering copper, using the rosin same as you would solder. In fact, "soldering" the crack, over the soap, with rosin.

But there is always danger that rosin will break open as the car receives strains due to traveling, and should the rosin crack open, it will fail to prevent leakage. To get rid of this trouble, I mix a quantity of oil with the rosin. Almost any mineral oil will answer, except coal oil, which will do the trick, but which is not as good as lard or lubricating oils.

Melt the rosin in a can or in a ladle, and stir in about one-half its volume of oil. Stir the mixture well and place one side to cool. You had better keep it in a dish which can be covered to exclude dust. If you make this mixture about as soft as beeswax, it can be "soldered" upon a crack, and will be found so tough and elastic that it will yield to motion of the car without cracking in the least.

If you make the mixture thinner, you will have what is known in paper mills as "lagging wax" and is used for fastening strips of felt or canvas upon pulley faces when it is necessary to increase the pulley diameter very slightly in order that the web of paper may be drawn through the paper machine at exactly the right velocity.

Lagging wax also forms a fine dressing for damaged fingers. Just daub a bit on a rag, wind it around the finger and the bandage will stay in place until "the cows come home" and the wax proves very soothing and healing to most flesh. Thin this stuff still more with oil, and you have a pretty good substitute for sticky fly paper. You won't catch many flies with it this time of the year, but in summer, thinned lagging wax, spread upon pieces of board, has done duty many a year before "tanglefoot" fly paper became a household necessity. Try lagging wax. It's great. It's fine also for chucking a small piece on the face plate of a lathe.

MAKING SMALL BEARINGS.

How it is Done by Means of Crucible, Lathe and Drill Press.

From J. N. Bagley, Nebraska.—Scarcely a day goes by but we need in the shop a piece of brass or bronze for making some machine bearing. To carry

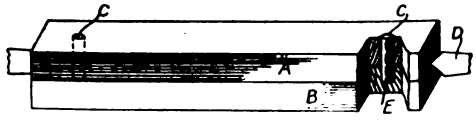

Fig. 1.

a stock of bronze involves quite a little capital, although many times a cheaper bearing material will answer the purpose. Every shop having a turning lathe and drill press is equipped for making small bearings and many times a bearing that is worn can thus be replaced with a new one as quickly as the old one can be repaired and with far better results. Of course, this home-made bearing metal is not supposed to be as good as the special non-grain on the market, but it is a good metal for ordinary work, such as lawn-mowers, corn shellers, threshing machines and similar machines. For automobile bearings, such as spring toggles, steering knuckles, etc., it will answer very well. Such parts as the wrist-pin bushing and other parts requiring great speed and strain, should be made of the very best bearing bronze.

One should always save the old bronze boxings taken from machinery and not sell to junk peddlers, as the price one gets for it is not the value of a single repair job one can get by turning down an old bearing. This old metal can be melted and molded into round stock which can be made into almost any shape desired with the aid of an inex-

Digitized by Google

pensive mold and an ordinary forge fire. The fire should be made deep and well lighted after which the crucible should be heated slowly until the metal begins to melt when piece by piece may be added until the required amount is melted. There are a number of different crucibles on the market. Some are of black lead, others of graphite, and some are of sand. They are not expensive, and one could have a half dozen different sizes and use only the size that would come nearest answering the requirements. When buying the crucible it is a good plan to get a lid for each, as by covering, much heat is

Fig. 2.

held in which otherwise would radiate out at the top, especially if the crucible is a trifle large. Then next in order will be a pair of tongs to fit each of the crucibles, for it is a little awkward to handle them without tongs made to fit, and besides when the metal is ready to pour, it should be done at once instead of looking about for something to handle the crucible with. The metal should be poured at once and not in a small stringy stream, as it will cool sufficiently to stop flowing before it has flowed over the entire mold. The gate above the mold should be large enough to force the metal into all the parts of the mold.

Next in order will be to know the size of the stock to make the finished bearing. Now with a couple of pieces of white pine fastened together with dowel pins, as shown at C, in Fig. 1, we will proceed to make the pattern. The blocks, A B, should be enough longer than the stock is wanted to allow for an impression in the mold to carry the core, as it is better to core the stock than to make it solid, as it takes a little less time to machine it. The dowel pins should not extend entirely through the second piece as shown at E, and should be arranged so that in case the top half of the pattern be lifted off, it could be replaced with the ends the

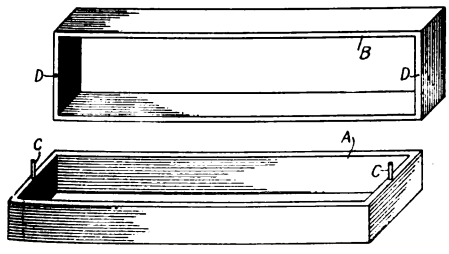

Fig. 3.

same as before. The pins should be made fast in half A, and slightly looser in B, so that when the part A is removed the pins will remain in it. Now by placing the entire piece in the lathe and the outer end supported by the tail stock center, as at D, we are ready to turn it to the required size.

In Fig. 2 we have the finished patterns so far as the turning is concerned. The parts A and B are held still by the pins C. The projection at either end D, is left the size we want the hole cored through the stock. Of course this can be arranged to meet requirements while making the pattern.

Now that we have the pattern turned, we will give it a coat of hot beeswax, so that the mold material will not stick to it when we are making the mold. These are best handled not too long; say, anywhere from 6 to 10 inches works very well, and in case the bar cast is quite large it makes quite a little metal to melt in a forge, although if a well-banked fire is made it will be no trouble. Now in making the core or the pattern for the core, it should be at each end exactly the same as the ends of the pattern so that in supporting it in the mold it will fit exactly where the pattern comes out. In case the core is to be quite a little larger in the stock, the core could be made larger except the ends D, and this would save a little time in making an extra pattern for a piece of stock with a larger hole, and yet at the same time have the same outside diameter.

Next in order will be a box for a flask. This can be made of thin lumber and should be roomy, especially if sand be used for molding, or plaster of paris. I would recommend the latter as many casts can be made without destroying the mold unless some accident befalls it. The writer has made as high as fifty casts of a single piece and yet had a very good mold. We will need in this case two separate boxes, as we will call them, with neither top nor bottom, as shown at A, B, in Fig. 3, and into each end of

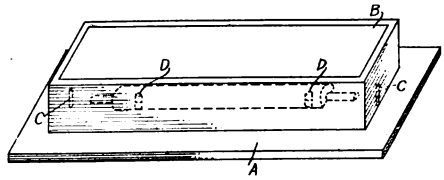

Fig. 4.

the "drag" or bottom half, place pins C, to allow the cope or top to be replaced exactly each time.

These parts should be well fastened at the corners to prevent them racking when handled. It is not a bad idea to place a few screws from the outside of the cope and drag, allowing them to stick through to hold the material that the mold is made of, especially if it be plaster of paris, as in constant use it wlil slip out of the frame, and when it does not have protection at the corners, it will chip away very easily.

We are now ready to make the mold. In the first place it will be necessary to obtain a board, A, Fig. 4, to lay the half of the pattern on while making the lower half of the mold. Now make small holes at D, in the board for the pins in the pattern to set in while making the half mold. Then when placing the half of the flask over the pattern on the board we find there are a couple of pins in it that hold it up and it is necessary to make holes to allow it to rest flat on the board as at C. Now we have the pattern securely fastened by the pins on the board A, the half of the flask B resting squarely on the board. Mix up a quantity of plaster of paris which will fill the space and is as thick, will push well into shape. It should not be thin and watery but should have plenty of body. Fill the box, being careful to force it well into all the cracks and corners and around the pattern. This will complete all that can be done until it sets and dries, save stroking of the surface which should be done as soon as finished, and at this time it would be well to take a sharp instrument and mark on the top the size and such other information as will be useful later on.

After leaving it in this manner for a day, if pos-

Digitized by Google

sible, turn it over and remove the board from the pegs and we have it as shown in Fig. 5. The lower half of the pattern is in the "cope." Over this place the remaining half of the pattern and we are ready for the other half of the mold, except that some powder should be used to prevent the parts sticking together and I have found that powdered graphite does very well and can be found in almost every shop. Sprinkle this or rather dust it over the sur-

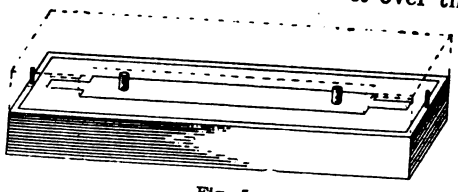

Fig. 5.

face of the already finished part before filling, after which a second batch of mortar can be mixed and the flask filled. Set away to dry and harden. It should be thoroughly dry before attempting to mold in it. As soon as it is dry, a gate with a sort of a funnel entrance should be made about center way of the top half of the flask. And over the top, it is a good plan to drill a few very fine holes to allow of the air passing out as the molten metal passes in. The object of having the funnel shaped entrance for the metal is to allow of the metal to be dumped rather than poured and to give weight to force the metal well into all the little crevices of the mold.

We will suppose all is dry and in readiness for the first cast. The next thing in order will be to place the core in position as shown at A, Fig. 6. As

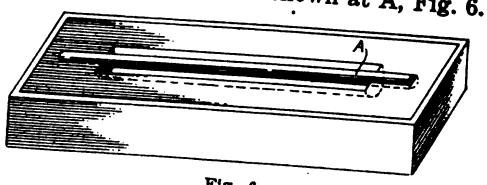

Fig. 6.

soon as the core is in place we are ready to place the top of the flask in position and clamp down or lay heavy weights at either end to prevent it raising or allowing the metal to crawl out around the edges. When the cast is made and cooled the "cope" may be removed carefully and the cast stock lifted from the "drag" or bottom half. Now remove the core with a chisel or by punching it to pieces with some instrument and the stock is ready to use.

These cores can be made of the same material as the mold or they can be bought from a foundry and broken to the proper length. In Fig. 7 we have a drawing of a finished cast of stock as it will appear after it has been removed from the mold and the core knocked out. In Fig. 8 we show home-made core box. A hole is made through the two blocks which are pinned together as shown at D. The top half A, can be lifted from the bottom half B, as soon as the core is dry. The hole in the core box C, will be the size of the finished core when it is removed from the box.

In case some special size or shape is wanted it can be made up at odd times and the time will not be lost. This need not be confined to the casting of brass alone as it works equally well for casting babbitt stock for duplicating die cast boxes for connecting rods of many automobiles as well as for the boxings of gasoline engines.

If one cares to make small brass castings oth than those just mentioned it would be well to ord from some foundry a bushel or so of good moldin sand and have it on hand. Many times a small bras casting can be made which would take weeks to g from the factory. Likewise, a small casting of iro or an engine or a cream separator can be duplicate in brass and the customer continues using the ma chine, where if he had to wait for one to arrive fron the factory it would take many days and might mea many dollars to him.

I remember how quite well pleased a customer was when he came to a shop with a small broken casting and he could not get repair for it, as he had purchased the machine from a small mail order concern that had gone out of business. He was anxious for me to fix it up in some manner. I told him if he would spend his money at home next time I would try and help him out of his trouble, although I would be unable to get it for some little time. He was satisfied with any sort of a promise as the machine had cost him quite a sum. When he had gone I set about to solder the broken parts for a pattern and in course of a couple of hours I had the

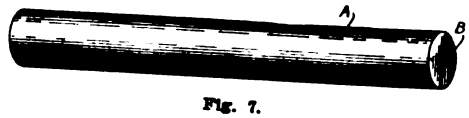

Fig. 7.

part cast in brass. I machined and polished it up and it looked even better than the piece he had brought to me. He came in the next morning and when the piece was delivered and I told him the bill would be two dollars he gave me an extra one, which indicated he was pleased with the job. Since that time I have made him many castings of brass for his neighbors.

One day he wanted me to make a casting for a hay bailer. "Now, Mark," I said, "you are imposing on good nature and if I have to do anything like that you can go back to the mail order house." He laughed but told me he guessed my suggestion was a little strong. The large casting we welded with the welding machine and again he was surprised at

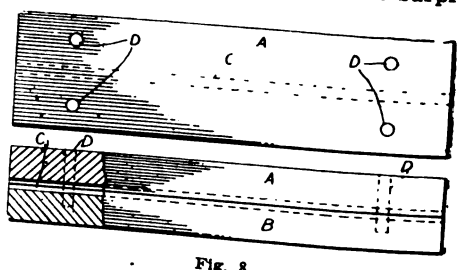

Fig. 8.

the welding of cast iron. As he paid the bill he said, "I 'low as how you fellers can fix most anything; thought I had you stumped this mornin'."

Inflation Dangers.

Over-inflation causes injurious vibration of the whole car. Under-inflation hastens breakdown, but gives easy riding. Heavy cars wear the treads down rapidly, light cars the sides. Drive wheels wear the tires one-fifth faster than front tires. There is no certain mileage in any tire. It's the driver's care that counts.

BATTERY CHARGING.

Another Rectifying Device for an Alternating Current Electrical Supply.

Simple forms of rectifying devices have already been published in this magazine and we have had scores of letters either approving or criticizing them. Plainly and conclusively, it will pay no one to either purchase or make a recharger for his own use only, and unless the garage or repair shop workman, has plenty of time and constructive ability on his hands, he would better purchase a rectifier than attempt to build one. However, here is a description of a simple rectifying device taken from the Autocar of England, which is given for what it

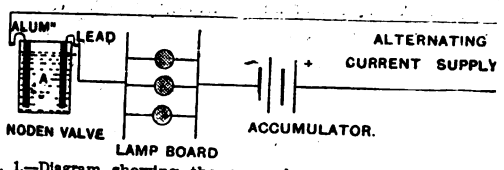

Fig. 1.—Diagram showing the general arrangement for accumulator charging from an alternating current by means of the Noden valve.

is worth. It may be added that we know absolutely nothing about it except as stated:

"Accumulators or batteries in spite of their somewhat robust outward appearance, are, as a matter of fact, delicate pieces of apparatus at the best of times. Given fair treatment and careful handling the user will be more or less repaid by faithful service, but neglect a battery, permit some cells to be overcharged, and others undercharged, exceed the maximum capacity on frequent occasions, allow sulphating and short circuits to develop, and very soon it will be found advisable to replace that particular battery by a new one.

"A battery cannot be regarded as a mechanical device; it stores energy in a chemical form, and chemical actions are necessary to effect this storage, or, on the other hand, to release the energy as the energy of a current. The adding of a little water from time to time, in the same manner that oil is usually added to the engine, will not suffice to retain a battery in good working order and condition. Each separate cell requires individual attention, and if it be found to be suffering from any of the numerous battery complaints a period of treatment on a charging board is essential.

"For battery charging a direct current is required, and to obtain this, when the only available supply is an alternating one, it is necessary to rely upon some form of rectifying device to produce the required transformation. Many such devices, notably the electro-magnetic and the mercury-vapor rectifiers, are on the market, but owing to their rather complex character and somewhat high cost motorists have been slow to adopt them. There is, however, a pressing demand for some such device, and the following notes, dealing with the construction and operation of a form of rectifier known as the Noden valve, may be of interest.

The Noden Valve.

"The Noden valve is extremely simple in construction, and a serviceable model can be quickly made at a trifling cost. The necessary materials comprise an active pole consisting of a rod or plate of pure aluminum and a further plate of lead, iron, or carbon to form the inactive pole. The dimensions of the poles are of no particular importance, and for small cell charging an aluminum plate 10 in. x 1 in. x ⅛ in., and a lead plate 10 in. x 2 in. x ⅛ in., will be found to give excellent results. The liquid required is a saturated solution of bicarbonate of soda or similar alkali, which, together with the metal rods, may be conveniently retained in a glass or stone jar some 5 in. or 6 in. in diameter, and the valve will then be ready for use.

"If a valve constructed in the above manner be connected in series with an accumulator, or other source of direct current supply, it will be found that a steady current will flow when the positive pole of the accumulator is connected to the lead plate of the valve; but that, on the other hand, if the positive be connected to the aluminum plate, the current will rapidly fall to practically a zero value.

"This very remarkable property of the rectifier is partly due to the collection on the aluminum plate of the gas formed during the passage of the current, but mainly to the fact that the gases attack the plate, combining with it to a certain extent and forming upon its surface a non-conducting layer of aluminum hydroxide.

"If an alternating current be now substituted for the direct one previously employed, the same actions will take place.

"Currents will be permitted to flow in one direction only, namely, from the lead plate to the aluminum one, all currents in the opposite direction being checked, the result being the passage of a pulsating direct current through the circuit.

"The rectifier behaves in exactly the same manner as a non-return valve, opening to permit the flow of current in one direction, but closing as soon as the current tends to flow in the opposite direction round the circuit, one half of each alternation being suppressed and the other passing through the cell or cells on charge.

Use of the Noden Valve in Practice.

"In practice the valve should always be used in series with a lamp bank, similar to the ones em-

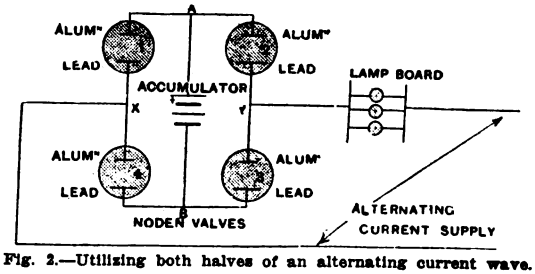

Fig. 2.—Utilizing both halves of an alternating current wave.

ployed in ordinary direct-current charging sets, for the current may then be conveniently varied to suit the charging requirements of the different batteries in use.

"Fig. 1 shows the general arrangement for accumulator charging from an alternating current supply, the necessary rectification being produced by the valve A. It is important to note that the negative pole of the accumulator must be connected to the lead plate of the valve in order that the charging current may always flow in the correct direction, the current, as previously pointed out, being a pulsating but direct one. In Fig. 2 four valves are shown connected up for charging purposes. Such an ar-

Digitized by Google

rangement is a more efficient one than that shown in Fig. 1, for now both halves of the alternating current wave may be made use of.

"Thus, assume for the moment that X is the point at which the current first enters the circuit. Such current will be limited in direction by the action of the valves, which will only open to permit of a flow taking place from a lead plate to an aluminum one. The current will, therefore, flow through valve 1 to A, and, being checked by valve 2, will pass through the accumulators to B, and continue from this point through valve 3 to Y and back to the mains.

"Again, when Y is the point of entry of the current, the circuit will be maintained through valve 2 to A. At this point valve 1 will check the flow, which must then be continued through the accumulators to B, and thence through valve 4 to X and back to the mains.

"The charging current is thus maintained in the same direction throughout, and it will be clear that both halves of the alternating wave are made use of. In conclusion, it may be mentioned that, in order to prevent the solution from creeping, it is as well to cover the top of the jars, as well as the plate to which the metals are fastened, with hot paraffin wax, and, further, occasionally to renew the solution."

THE MAGNETO.

From a Paper Read Before the Coventry, England, Engineering Society.

By Arthur P. Young, A. M. I. E. E.—The impetus given to the gasoline motor and allied industries some years ago by the advent of the high tension

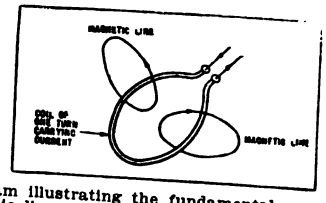

Fig. 1.—Diagram illustrating the fundamental conception of magnetic lines linked with a conducting circuit.

magneto is apparent to all those who have watched the extraordinary developments that have taken place in the last decade. Prior to the outbreak of hostilities, this country obtained almost the whole of its magneto supplies from Stuttgart, in Germany —due seemingly to a short-sighted policy on the part of British motor manufacturers in not encouraging a home industry—and one immediate effect of the war was, therefore, to cause electrical appliance manufacturers to turn their attention seriously to this development.

The new industry that has thus come into being is of national importance, and it is gratifying to be able to record that several electrical firms of this country have undertaken the development and manufacture of magnetos, so that in the very near future the English-made magneto should entirely displace the imported article. Prominent amongst those who are engaged in this work is the B. T. H. Co. of Rugby, a firm of electrical engineers having admittedly a world-wide reputation. Some two years ago they interested themselves in this problem and during the intervening period much important research work has been carried out in their laboratories. The result of these investigations is reflected in the design of the sixteen different types of magnetos which have been developed at their Coventry works with the object of ultimately producing quantities sufficient to meet the demands of the British market. By permission, I am able to make use of some of the experimental data which the company have obtained.

My object in writing the paper, of which the following is a summary, was to throw some new light

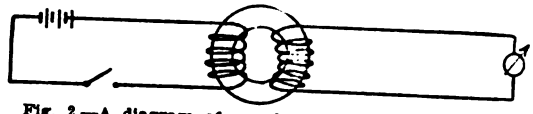

Fig. 2.—A diagram of an elementary induction coil.

on the action of the magneto—which, after all, is purely an electrical machine—and I have endeavored to treat the subject in the following lines in such a way that those whose knowledge of electrical matters is rudimentary will have little difficulty in understanding my meaning.

The Induction Coil.

If we study closely the steady development that has culminated in the present high-tension magneto, we shall find that it had its conception over eighty years ago, when Michael Faraday, an Englishman, made known to the world his epoch-making discovery of electro-magnetic induction in the autumn of 1831. This is not only the basic principle underlying the construction of the magneto, but also the solid foundation upon which the great electrical industry has been built up.

Farraday gave to posterity a sound mechanical method of producing an electric current in a circuit. Briefly, if the number of magnetic lines (called the flux) linked with a circuit—as depicted in Fig. 1—be changed, a voltage is induced in the circuit which is directly proportional to the rate at which the change occurs. With a closed circuit, a current will flow around it as a result of the induced voltage.

Following on Farraday's discovery, it was relatively easy to construct an "induction coil," which

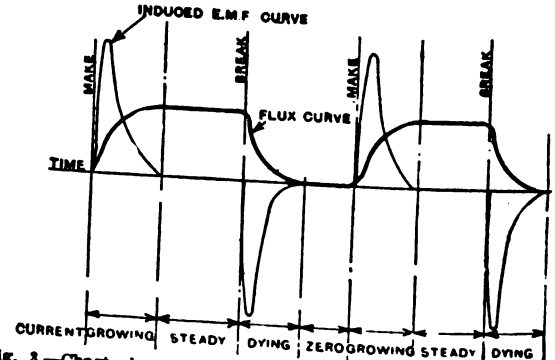

Fig. 3.—Chart showing the relation between the induced E.M.F. and the flux curves when the primary circuit is closed and opened.

was perfected by the Frenchman Ruhmkorff some sixty years ago. Fig. 2 represents diagrammatically such a device, and, if the battery be deleted, we get the connections of the magneto reduced to their simplest possible form. The curves given in Fig. 3 show what happens in the secondary when the primary circuit is closed ("make") and opened ("break") and they express graphically the formula given above.

Digitized by Google

To cause an electric spark to jump across the air space of ½ inch between needle points, a pressure of about 13,000 volts has to be applied.

In an induction coil or magneto, therefore, the induced voltage has to be exceedingly large, which can only be done by:

(a) Having a very large number of secondary turns (S).

(b) Making the flux (N) linked with these turns as large as possible.

(c) Using a contact breaker in the primary of such a design that at "break" this flux is made to die away as rapidly as possible.

These results are achieved in the induction coil, and also in the magneto. As will appear later, the magneto is simply an induction coil which is able

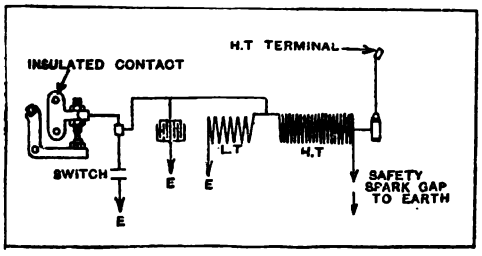

Fig. 4.—A diagram of the connections of a B.T.H. magneto.

to operate without a battery, by virtue of the fact that it rotates in a magnetic field of varying strength, and thereby has induced in the primary winding the requisite current.

The Action of the Magneto.

Considered purely as an electrical machine, the magneto consists of three essential parts:

(a) A magnetic system comprising a permanent magnet, or a combination of permanent magnets, to the poles of which cast iron pole pieces are secured.

(b) An armature made up of a partly laminated iron core, and provided with a primary and a secondary winding. This rotates in the space between the pole faces.

(c) A contact breaker, which is rigidly secured to the armature shaft so that it rotates with it. The function of this part is to short circuit for a certain period, and then suddenly open circuit, the primary winding, when the armature is in predetermined positions.

A simple connection diagram for a B. T. H. Co. magneto is given in Fig. 4.

The flux change in the armature core corresponding to a movement of the armature through nearly one-half a revolution is shown diagrammatically in Fig. 5 by means of four figures. Taking the positions in the order given, namely, 1, 2, 3, 4, the variation of flux through the armature core is of the following order: 4, 6, 4, 0.

The point to be noted is that when the armature moves to the position 4, the flux linked with the windings is suddenly withdrawn and made to bridge the pole tips. This position I shall call the "dead center," and, as the flux change is so rapid, the induced voltage in both primary and secondary must attain a maximum at this instant. As there are two "dead centers" in each revolution, the induced voltage is alternately positive and negative, the maximum point occurring after each half revolution.

Fig. 6 shows the voltage wave obtained experimentally on a B. T. H. Co.'s type "M" machine at a speed of 1,000 r. p. m. The flux wave has been calculated from it, and shows that the maximum flux through the armature core is as high as 31,000 lines. In each magnet this corresponds to a flux density of 5,250 lines per sq. cm., which speaks well for the high quality of the magnets used in this particular machine.

The maximum voltage attained in the primary at 1,000 r. p. m. is 27.2. In the secondary at this speed the voltage would be 27.2 multiplied by about 50. This voltage is therefore 1,360 volts. At a speed of 2,000 r. p. m. it is very nearly 2,500 volts. It must be remembered that this figure gives the voltage due to relation only. Superimposed upon this we have to consider a much larger voltage which occurs at the instant when the primary circuit is opened by the contact breaker. That is, we have to take into account the induction coil effect.

Magneto Operating with Primary Short Circuited Continually.—The induction coil effect depends upon the value of the primary current at "break." For the machine under consideration, the value can be determined from the three short circuit current curves given in Fig. 7, and which have been calculated from the voltage wave. A careful test, however, made at 2,000 r. p. m. checked the curve for this speed, thus showing that the method of calculation employed is reliable.

Magneto Operating Normally.—As the speed increases the maximum value of the current wave is displaced more and more beyond the "dead center."

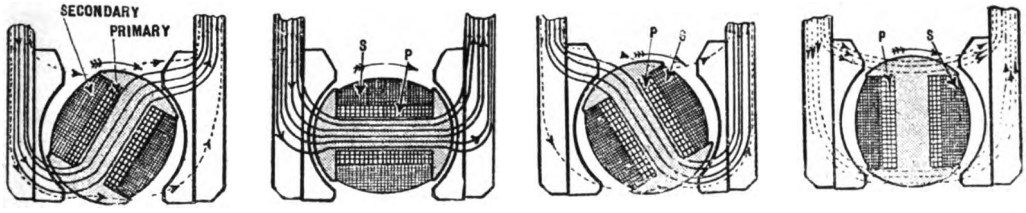

Fig. 5.—Diagram showing the flux changes in a magneto armature due to rotation. In position 4 the armature is in position of dead center.

That is, the lag increases, reaching 50 degrees at 2,000 r. p. m. It is important to note, also, that the actual maximum current does not change appreciably over the range of speed chosen. After a considerable amount of research work, the parts are now being produced in this country, and very careful tests which the B. T. H. Co. have made show that as regards insulating properties, durability, and power to withstand extreme variations in temperature, they are quite equal to the German material.

Magnets.—Before the outbreak of the war practically all the permanent magnets used in this coun-

Digitized by Google

try for a variety of purposes were obtained from Germany, and English users generally were only too prone to believe that a satisfactory permanent magnet could only be produced in that country. During the past few months, however, there has been sufficient evidence to show that such an idea was entirely false. To produce satisfactory permanent magnets great care only is necessary in the treatment of the steel, particularly during the hardening processes. There is an abundance of literature dealing with the subject, and it is interesting to note that, whereas for the past years the industry has been entirely in the hands of the Germans, the classical treatise dealings with the whole subject of permanent magnets is of French origin, and was prepared some years ago by Madam Curie, who, as is perhaps well known, collaborated with her husband in the research work which resulted in the discovery of radium.

The B. T. H. Company have recently carried out very extensive tests on permanent magnets designed for magneto work and manufactured by English suppliers, and there seems little doubt but that the permanent magnet industry in this country will increase at a very rapid rate and maintain its position by displacing the German-made article, even after the war is ended.

It is, of course, understood that under normal working conditions the primary is not continually short-circuited, but is alternately short-circuited and open-circuited by the contact breaker. I have adhered to the simpler way of looking at the problem, however, because in a great many cases the value of the primary current at "break" as determined from the short circuit current curves is substantially correct. In other words, if the ratio be large, then the short circuit current curve for the period of time in which we are interested agrees very closely with the actual primary current wave. In the case of magnetos designed to give one break per revolution, and even for those giving two breaks per revolution, and provided with flat segments on the timing lever, this method can be safely applied up to speeds of 1,000 r. p. m. At higher speeds the actual "break" current is somewhat greater than that given by the short circuit current curve.

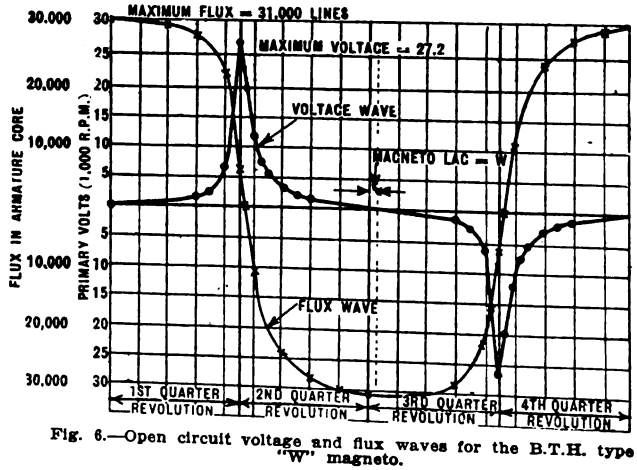

Fig. 6.—Open circuit voltage and flux waves for the B.T.H. type "W" magneto.

For magnetos giving two breaks per revolution and having relatively long segments (as in the case of the Bosch type Z4, for example), the ratio is very small, and this method of treatment cannot be applied. It would be necessary in such cases actually to calculate the primary current waves which, however, could be done by following out the method of analysis employed to determine the short circuit current curves already referred to.

Sparking Voltage.—The spark results, of course, from the voltage suddenly induced in the "secondary" at "break." The voltage between the plug electrodes at the instant before the spark occurs (called the "sparking voltage") is very much greater than the total voltage induced in the secondary, as

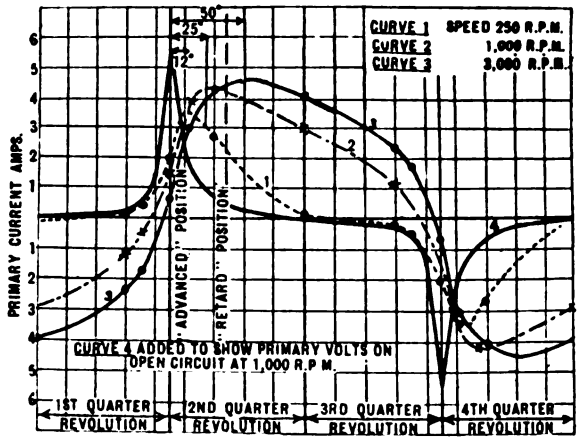

Fig. 7.—Short circuit primary current waves for B.T.H. type "W" magneto.

determined by the method indicated under sections (2) and (3), owing to a rise which results from the sudden application of a large voltage to a circuit possessing self-induction and capacity. This effect is one that is well known to electrical engineers.

Tests made on the B. T. H. Co.'s type "W" machine, already referred to, show that the sparking voltage is approximately 10,000 even at very low speeds. That is, a spark can be obtained in air between needle points 10 mm. apart. This figure is quite equal to that obtained with a standard type ZF4 Bosch machine suitable for the same class of service. As an approximate rule the sparking voltage can be assumed to be proportional to the primary current at break.

An Up-to-Date Garage.

The St. Albans Foundry and Implement Company, of St. Albans, Vt., have completely rebuilt and enlarged their garage at 43 Lake street. The garage occupies a portion of the company's main building which is of fireproof construction, the first story being built of solid brick and the second story of metal lath and cement on a wood frame. The entire interior of the garage department is of steel and all floors of cement, except those in the ladies' waiting room and the stock and show room. These rooms have hardwood floors. The large storage room it is estimated will accommodate sixty or more cars, the entrance being eleven feet wide. The main repository, repair department, stock and show room and ladies' waiting and rest room are all located on the ground floor. Entrance to each may be made from the street as well as from the main storage room or repository. The automobile repair department is in the rear of the main storage room.

Heat to all these rooms is furnished by the large steam boiler formerly used as a power boiler for operating the company's entire plant, which is now run by electricity.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1554 Starting Queries.

From a Reader, West Virginia.—1—I would like to know if you can start an auto with a Splitdorf, low-tension magneto, without batteries. I have a low-tension Splitdorf magneto and coil and switch marked "bat. off mag." Car will only start on bat. 2—I see in your January number writings by James F. Hobart, M. E., that he would not have a magneto if he could not use it in starting. Would he please tell me how to use the above in starting? 3—In case you have a good hot spark at plugs, and motor will not start, what could be the cause of not starting? I primed the engine but it still refused to start. 4—Can you tell me where I can get a good correspondence course in electricity?

Reply.—1—You cannot start your motor with a Splitdorf low-tension ignition magneto for the reasons that it does not generate direct, but alternating current, the former only being suitable for charging storage batteries, and that it would be impossible to run an alternating current magneto as a motor with direct current supplied by a storage battery. To make an electric starter three things are essential: first, some means for generating electric current; second, some means for storing this electric energy, for when the motor is still, current can not be taken from the generator, hence the storage battery, and third, a motor supplied from the stored electric energy to run the electric motor until the engine will take up its regular cycle. 2—Mr. Hobart simply expressed his views. There are plenty of others well informed in automobile matters who would not use magnetos for ignition, preferring so-called single-spark battery ignition system, the current being generated to charge storage batteries. There is another class who would not have a car that did not have dual, duplex or double ignition, both engine timed magnetos and batteries. There are some engines that are so structurally designed that it is well nigh impossible to start with a magneto. Mr. Hobart might well have added that he would not own a motor that he could not start on magneto. The ignition system he described is by no means a modern one. 3—Dozens of causes, but among the most common, providing the engine is properly timed, both in valve operation and ignition, the following: Very cold weather; hard-to-vaporize gasoline; weak exhaust valve springs; air leaks past inlet valve springs; too much gasoline; impaired compression, etc., etc., ad infinitum. 4—We make it an inflexible rule never to advise or indicate any preference, accordingly we must decline to make specific reply. If you will indicate the branch of the electric study you desire to take up we might select a list of books for you to purchase that will give you an elementary information which you would probably follow up in some definite line, such as electric ignition, electric lighting, electric propulsion, etc. For one to absorb the entire gamut of electricity by correspondence seems to us an impossibility, when an electrical course in a university would take several years, and then would school one in the principles and theory only.

1555 Piston Ring Clearance

From William H. Beers, New York.—I intend to put Wasson rings on my car this spring and should like to know the proper end clearance to give them. The car is a Flanders 20, 1912 model, with new cylinders last year. Would it be best to replace all the rings with Wasson or not?

Reply.—Wasson piston rings should have about .010 inch end clearance at the smallest diameter of the cylinder bore. Two thicknesses of ordinary newspaper makes a good measuring medium. We believe you should renew all rings while the engine is apart. You will probably find that the cylinders are slightly worn, for all they have been used but a single season.

1556 Rewinding Coils.

From A. G. Luyster, New Jersey.—I have under my care several gasoline engines. Every once in a while one of the spark coils breaks down. Is there any way that I could rewind an old one to have on hand for an emergency? Some few months ago a coil on my two cylinder opposed engine had a breakdown. This is not a vibrating coil and it has been running for three years straight. Will you kindly explain the cause of a breakdown and how to remedy it in an old coil?

Reply.—There is no way that you could rewind a broken down coil, for in the secondary wiring there is usually several thousand feet, or a mile or two of fine wire. It is cheaper to buy new coils than to attempt to repair defective ones. The cause of broken down coils is usually either a short circuit in the primary or secondary wiring, a punctured or perforated condenser, a broken primary wire, poor contact at the binding post, etc. If the coil is of the vibrating type, there may be vibrator troubles as well. If your coil lasted you three years it seems to us it has done pretty well. When you get a new one do not see how far you can make the spark jump with it and it may last you longer. We think we are safe in saying that 90 per cent. of all defective spark coils are ruined by the abuse above mentioned.

1557 Wants Increased Power.

From Dr. Ellsmer L. Piper, Pennsylvania.—I have been told of two ways in which the power of a Ford engine may be increased and wish to know if any damage might be done to the magneto or the engine. 1—One Ford driver has had ⅛ inch "milled" or "planed off" the cylinder head and by reducing the size of the explosion chamber, claims a decided increase in the power of the engine. 2—

Digitized by Google

Another Ford driver allows the vibrator, i. e., does not shunt them down in the regular equipment to act with a K. W. master vibrator and claims an increase. I am inclined to be skeptical on both points, but desire to submit the same to your Trouble Department, and will thank you for a reply in your next issue.

Reply.—1—A few years ago the Ford Motor Co. increased the clearance in order to slightly decrease the compression which in actual practice had proven too high. While you might get slightly more power there are other conditions to be considered, especially of pre-ignition, knocks, etc. You can take it from us as gospel truth that the present clearance in Ford motors is much nearer what it should be than what some experimenter thinks it should be. 2—In order to be charitable we say that we think your informant has been able to delude himself into the belief that he gets more power. We are even more skeptical, if this were possible, than you. Manufacturers of master vibrators should be best informed as to the proper way to connect their product in a vibrating ignition system.

1558 **Lubricating Trouble.**

From Lawrence W. White, Massachusetts.—1—I have a 1908 Lancia, 4 cylinder, 4 speed runabout, motor 3½x4, built in Italy, which I have owned for about a year. I find oil consumption very heavy, about 300 miles per gallon. I use Mobiloil B all the year and think I should get more mileage. The oil system is entirely force feed. What should I normally get? On gasoline I average 19 miles per gallon, which I consider good. 2—From the exhaust end of the muffler I removed a heavy carbon deposit and for experiment touched a match to it and found it burned quickly. Do I not run the risk of the entire muffler catching on fire? The muffler has no pipe at its outlet, but exhausts about the middle of the under part of the car. 3—The tires are clincher demountable (Machelin) and are metric sizes. I find the nearest actual size in American sizes is 32x4, and it takes two strong men to put on a new shoe. Why can I not use a 33 or 34 by 4 on these rims? 4—By lengthening the intake valve push rods, can I not secure a bigger charge of mixture and increase the power considerably? As it is, the engine is too small, and the car is geared too high for American roads, although on English and French roads, which are uniformly smooth and with gentle grades, this car is speedy and economical. 5—Do you recommend a heavy oil for transmission or a non-fluid oil? In warm weather the gear oil appears to get too thin, and in cold weather the non-fluid seems to solidify and one runs the risk of getting no lubricant on the shaft bearings. If you will answer my several questions, I shall be greatly indebted to you and wish to thank you in advance.

Reply.—1—If after seven or eight years' use you are able to run 300 miles on one gallon of oil we think you are doing pretty well. Nineteen miles on a gallon of gasoline is nothing unusual. 2—Yes, there is some danger of the accumulations of carbon and unburned oil taking fire in the muffler. It should not do any great harm though. Until you have new pistons and rings fitted to re-ground cylinders you cannot expect to reduce oil consumption which now clogs your muffler. 3—Absolutely nothing to prevent your using oversize tires, but you should not use larger than 33 inch diameter. 4—No. 5—It depends entirely upon the design and construction of the transmission. One should not use a grease or non-fluid oil of the same consistency in winter as in summer. Use as thin an oil or grease as you can without its leaking out.

1559 **Rusting Rims.**

From James Harazim, North Dakota.—I want to ask a favor of you. I would like to know what to do for G. D. rims to keep them from rusting on the face of them. The castings will rust and get vulcanized to the rims so they are hard to get off. I polish them every time I take them off with sandpaper, but as soon as they get damp or wet they rust again.

Reply.—Probably painting them with black asphaltum varnish P. B. insulating paint, shellac or some waterproof varnish will do the trick, or you can use graphite. Sandpapering them only presents a fresh surface to rust quickly.

1560 **Gas Saving.**

From H. A. Van Kuren, Pennsylvania.—1—I am experimenting on a gas saver on my Ford car, similar to the same advertised in your publication. In the first place, do you know them to be much of any value? 2—I am connecting common ¼ inch brass tubing in the manifolds above the carburetor (Holly), giving it one wind around the exhaust pipe, extending it on up the steering column port-way with air valve on end. Will it be better to have hot air or cold to enter and why? 3—With such an arrangement will hot or cold be permitted to enter the intake, and why? I have tried this device temporarily and the speed increases possibly 15 per cent. The motor running idle was not tried on the road. The air must be gauged in proportion with the speed.

Reply.—1—Any device which will more perfectly proportion the gasoline and air should result in economy in fuel, and providing the engine is run all the time with fixed throttle opening, as is possible in a boat engine, manual control of an auxiliary air supply gives more power. This is the only reply we care to make to this query, except that such a device if absolutely positive, automatic in its action, and that would reduce the vacuum in the inlet manifold the correct amount, would be perfection. 2—We do not know that it will make much, if any, difference. If the gas in the inlet manifold is too warm, cold air would undoubtedly help it, and vice versa if the gas is too cold hot air should help it. The effect in either case would not be great, owing to the small area of a ¼ inch brass pipe, which is about one-tenth of the area through the carburetor throttle. 3—We are afraid we do not understand this question. Your statement that "the air must be gauged in proportion with speed," is a little indefinite, as this would depend upon whether the car was running free on a level road, partly throttled, or climbing a hill with throttle wide open. It would be better, perhaps, to say that the auxiliary air should be in proportion to the engine's demand for gas, less the air which leaks past the inlet valve stem bushings, another complexity, and a more serious one with gasoline growing heavier and heavier, and harder to vaporize as a result.

Digitized by Google

1561 **It Knocks at Times.**

From S. R. Newton, North Carolina.—1—I have a Ford touring car, 1914 model, run about 7,300 miles, which has a knock which seems to be in the No. 2 or 3 cylinder. I have had the engine top off but cannot discover the trouble. It is worse at times. It will run sometimes for 15 to 20 miles without a perceptible knock, then it will begin again. I have taken the carbon all out so I know that it is not the trouble. When it is knocking it doesn't make any difference where the spark lever is—whether it is advanced or retarded. The more gas I give it the more the knock. I have an air friction carburetor on my car. The knock is the same whether going on hard pulls or on level stretches. I have never had the car entirely down. 2—How much clearance should there be between valve stems and push rods? 3—Do these cup valve stem adjusters do the necessary work?

Reply.—In the hands of an experienced motorist an engine with a removable cylinder head is extremely convenient construction. Its serious disadvantage is from the fact that as soon as some fault develops somewhere in the engine or transmission—off comes the head. Knocks most frequently occur from lost motion, usually at the lower end of the connecting rods or in the center main bearing, and it is not at all surprising that you could not locate it by removing the cylinder head. Your description of symptoms shows lost motion probably in the center crankshaft bearing. You can reach this through the side plate hole in the crankcase. You may need a new bushing there. 2—About the thickness of a visiting card. 3—They should.

1562 **Clutch Inspection.**

From A. B. Carman, Iowa.—I have a 1910 Reo with a multiple disc clutch in the center of the flywheel, with only one thrust spring. The shank on which the spring is coiled extends back over the flexible joint in the drive shaft, to a point about one-half of an inch from the adjoining cone on the front of the transmission. This cone in the front bearing in the front end of the transmission case worked loose. I desire to inspect this bearing and see if any balls have been injured. I should also like to see the flexible joint and make sure same is O. K. What I desire to know is, what to remove first. Can this clutch be removed without removing the motor? The motor has recently been overhauled and is in excellent condition. Two or three times I have felt a very sudden jerk accompanied by some noise. The first time I felt the same I thought the drive shaft was broken, it was so sharp. This jerk seems to occur at times when the motor is pulling some load, but never occurs at regular intervals. The car may run five miles without it or it may only run one. There is no growling or grating, but just the jerk, then everything goes on well for some distance. I realize that it is practically impossible for you to locate the jerk exactly, but any suggestions you can give will be thankfully received. I have repaired many cars but this Reo beats my time.

Reply.—You should be able to remove the clutch without taking out the motor. You will probably have to disassemble the transmission, however, and disconnect the universal joint in the drive shaft. When you take the transmission down you will be very likely to find the cause of the occasional "jerk," which you mention.

1563 **A Generator Installment.**

From Joshua Conner, Delaware.—I am considering installing a generator on my Ford, 1913 T car, to work in conjunction with a 6-80 ampere Exide Westchester battery. Whose would you advise?

Reply.—If you install a generator you will need an automatic switch or relay, to prevent the current from escaping through the winding of the generator when the engine is not running, and when the voltage of the current being generated is less than that of the battery. It would perhaps be good advice for you to inquire from the makers of your storage battery what system they recommend, or from the maker of the generator you decide to buy, what automatic switch they suggest you use with your 6-80 Exide Westchester storage battery. We cannot advise you in the choice of a generator.

1564 **Engine Knocks.**

From R. D. Clark, Colorado.—I have a Buick model 31 which has been run 5,800 miles and am having some trouble with my engine knocking. Can eliminate the most of this trouble by retarding the spark. I had the cylinders taken down some time ago after the car had made about three thousand miles and the carbon taken out. I wonder if you can advise if it would be better to go through this performance again or can I use a good carbon remover to good advantage?

Reply.—In relation to the knocking in your engine, although it may be due to carbon deposit, yet, as you probably are aware, there are other causes for knocking. A fuel mixture that is too rich may cause a knock, or if a carburetor float leaks or is water-logged, it will cause it. Possibly, too, you may have a loose bearing after having run your engine nearly 6,000 miles. In case you find the trouble is due to carbon, we should hardly think it would be necessary to take the engine down again, but it would answer to use some good carbon remover for this purpose.

1565 **Starting Trouble.**

From Raymond Standish, Connecticut.—I have a Reo model "R. A." 1912, 30 h. p., cylinders 4x4½ inches, firing sequence, 1-3-4-2. It is equipped with a Stromberg carburetor, and a National Magneto model B-4. Sometimes it will start on the first half turn on magneto or battery (on battery the best) and then again I cannot start it at all. The carburetor is all right, because it runs fine when once started. I take out the spark plugs and lay them on the frame and no spark will show at all. I think the wires must be broken somewhere, but have been unable to find it, although I did find one broken wire under the switch on the coil box on the dash. I repaired it and am not positive that I got it right. Under the switch on the box the wires are like the diagram. I connected them as shown in the diagram. Is it correct? On the dash under the hood the studs are marked as shown. All wires seem to be in good condition and I cannot understand where the trouble can be. Would be very grateful for any information you could give me.

Reply.—If you get no spark it certainly explains the cause of failure to start. Your trouble is probably in the breaker box. The platinum contact points may need smoothing, adjusting or possibly renewal. Next time you disconnect your wires you will proba-

Digitized by Google

bly tie strings to them or otherwise mark them. Any one can take a watch to pieces, you know. Our advice is for you to send to the National Coil Co., Lansing, Mich., for their wiring diagram. From the diagram you submit we do not note anything wrong, except that you may have connected the plug wires incorrectly, or in improper sequence. In order for you to use battery ignition you must have the magneto properly and perfectly grounded.

1566 **Responsibility for the Damage.**

From C. G., Indiana.—A owns and operates a public garage and repair shop. B drives up in front of A's garage and asks to have his carburetor adjusted. A proceeds to make the necessary adjustments, and when speeding the engine to try the last adjustment the nuts slip off the studs of one of the connecting rods and damage the engine to the extent of about $150. Who is liable for this damage? The car did not belong to the party driving it, and he was alone in the car.

Reply.—A, who adjusted the carburetor, is not responsible for the damage, surely, assuming he did nothing else to the car. The responsibility for the damage rests entirely with whoever allowed the nuts to get loose.

1567 **Engine Inquiries.**

From A. R. Peterson, Iowa.—1—May a more powerful engine be placed in a 1914 model Krit touring car than a 22½ h. p.? 2—Which company puts out the most efficient engine? 3—What do you know about the Continental Certainty engines?

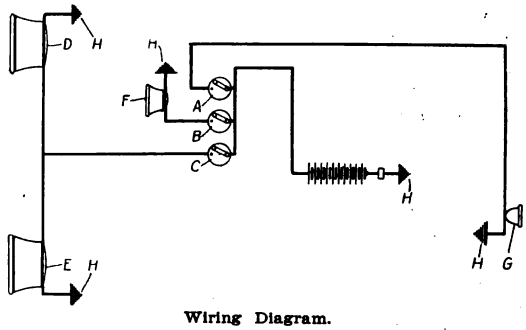
Reply.—1—Yes, if there is room for it, but we do not know if there is. 2—Every manufacturer claims his engine to be more efficient than others, and every such statement seems to be unchallenged. If we were to depart from our long fixed policy and make the statement that any one engine were any better than another we would receive deserved objections and complaints from the manufacturers of every other engine. Frankly, however, we are free to tell you that we do not know the name of the manufacturer, or of the engine, which is the most efficient, and if even we thought we did we would not dare to think out loud. 3—We know practically nothing of the engine you mention, but the Continental Motor Co., who probably manufacture this particular make, are responsible and reputable people, and are manufacturing and selling thousands of engines every year.

1568 **High Test Gasoline.**

From R. Cook, Indiana.—I drive a 1912, 55 h. p., 7 passenger Apperson car, which has a Stromberg carburetor. I have used a Standard and another gas which test 64 degrees with pretty good results, only in cold weather it was harder to start on. I changed to a gas which tests 75 degrees. The motor only needed a quarter of a turn to set it in motion, but after it runs for about 5 or 10 minutes, or in other words, until it gets warm, there are very fine bubbles which can be seen coming up from the bottom of the chamber. They get larger till it boils like water. The engine runs good till the larger bubbles come up, then it runs irregular and finally stops. As I did not want to use lower grade of gas on account of starting, I began to hunt for some device to stop the gas from bubbling, so I shut off the hot water, which goes to warm the carburetor, and placed a piece of tin (which was cut to fit) around the carburetor, up far enough and down far enough so that the hot air which the fan blows back from the engine could not come in contact with it. Now I run my motor on the standstill or on the road without any trouble with the gas.

I also drive a 1914 Ford car, which I am having a little trouble with and wish to know the reasons why. In the morning or after it stands for an hour or two, I start to crank it and have to spin it a dozen times or more before there is an explosion of any kind. It has the regular Kingston carburetor and I use a gas which tests 75 degrees. It makes no difference if it is on the magneto or battery in starting. The carburetor has been cleaned time after time, properly adjusted, tank and lines cleaned, spark plugs cleaned and points adjusted, and later replaced with new ones. The cylinder heads and pistons are free from carbon and I also cleaned the timer. After the engine gets started it runs fine. There is another trouble I have with it, once in a great while. The car goes along fine on the road and all at once the engine stops, so I get out and start it on the battery and then go on. When it stops running I turn it on the battery before the car stops and then it "takes to its heels again." Why is it?

Reply.—If you persist in using high priced and high test gasoline you must not use heated air nor hot water to assist in vaporization. You get easy starting, but there is not so much power in a gallon as there is in the heavier fuel. The trouble with your Ford T is that the gas is too rich when starting, the carburetor being designed to use a much heavier fuel. The size larger of carburetor would probably give better results for the reason that the fixed or constant air opening being larger the air would not have so high a velocity past the vaporizing nozzle. Earlier models of carburetors did not use so small openings as do present day models.



1569 **Lighting Diagram.**

From W. DeVere Blackmar, Michigan.—I drive a Ford automobile which has electric lights run from the magneto. I would like to convert my oil lamps into electric by using a storage battery. Will you please show me how to wire same so that I can use the tail light alone, or tail and dash together, or tail and side together, or all three at once. Will I have to use a one, two, three or four point switch? I would like to wire these in series as much as possible.

Reply.—Your storage battery is 6 volts and as 6-volt bulbs are to be purchased at almost any electrical supply store or garage, it will be much better to connect lamps in parallel, as in this case you can use 6-volt bulbs throughout. If you were to connect two lamps in series you would need 3-volt bulbs and if three in series the bulbs would have to be 2 volts each. If you use ground return, or the single-wire system you would ground one side of the battery to the frame of the car, using between the ground and battery a fuse block to protect the battery in case of a short circuit. The other pole of the battery could best be connected with three small single point switches, mounted in a row, as shown at A, B, C, one caring for the two oil lamps, D, E, another for the dash light, F, and the third for the tail light, G. This would

Digitized by Google

be very much simpler to wire and would give you any combination desired. If you only wanted one oil lamp all you would need to do would be to take out the other bulb. The diagram illustrates the wiring. You will note that each separate lamp has to be grounded, as at H, and also the battery, I, itself. In order to connect by the two-wire system the ground wire from the battery, instead of being grounded to the frame, would have to be extended

Wiring Diagram.

through or to the binding posts of all the lamps from which binding posts ground wires now lead, and no ground connections should be made from either battery or lamps.

1570 **Motor Vehicle Law.**

From F. M. Groth, New York.—Is there any clause in the New York State Motor Vehicle law saying that after a car is five years old the owner will have to pay only half the usual fee for it?

Reply.—There is no clause of this kind as far as we know.

1571 **A Missing Cylinder.**

From Paul Kuhnhausen, Washington.—I have a Buick, model 21, 1911 car, 35 horsepower, that is giving me some trouble. At times it will run fine for a while and then it will commence to skip on the second cylinder, and the plug will be covered with oily soot, while the remaining three will be clean. The compression seems to be good; also the wiring is in good condition. Do you think this trouble could be in the magneto? The magneto is a Splitdorf. I noticed in several of your late issues that some are having the same trouble with their model 10 Buick. I noticed in your January issue, on pages 57 and 58, Mr. Wm. Sisson's answer says to cut a little groove through the oil dip of the said cylinder, but this does not seem the proper remedy to me, as the machine ran fine when new. Now if you can help me out of my trouble, I will be very thankful.

Reply.—When an engine misses intermittently, as in your case, always in the same cylinder, the fault should not be laid at the door of the magneto for the reason that the same circuit breaker, same coil, same condenser and same distributor furnish the same strength of spark, up to the secondary cables connecting with the spark plugs, to both No. 2 and No. 3 cylinders. If therefore missing occurs in No. 2 cylinder as a result of faulty magneto it should also cause missing in No. 3 cylinder. There is, however, a slight possibility that it takes a stronger spark to ignite charges of gas in the No. 2 than in any of the other cylinders, but in every such case the trouble usually is structural, resulting in imperfect carburetion or lubrication. If structural it may be due to poorly fitting piston or rings, scored cylinder, leaks past the inlet valve stem, broken or weakened inlet or exhaust valve stems, sticking valves in this cylinder, defective plug insulation, leak of current from oil soaked secondary cable, etc. Scored cylinders and poorly fitting piston and rings are the most probable causes, which will allow oil to be drawn past them into the explosion chamber from which it will be splashed onto the plugs, short-circuiting them, and thus preventing sparks at the electrode. On the other hand, defective insulation of the plug wire or plug itself would cause an accumulation of oil on the plug as a result of the explosions not burning the small amount of oil that always works into any gas engine cylinder. Leak of air past the inlet valve stem would have a tendency to make the gas too lean, while weak or broken valve springs might prevent the valves from seating properly, allow burned gas to be drawn into the cylinder or drive out a portion of the properly proportioned explosive mixture. If cylinder is scored the only remedy is to have the Nos. 1 and 2 cylinders reground and new rings and pistons fitted, which should cost you for this work alone about $20. If piston and rings only need renewing the cost should be very much less.

1572 **Cause of a Thump.**

From Lawrence W. White, Massachusetts.—I have a 1909 four-cylinder Lancia, semi-racing car, with which I am having trouble. Owing to loose main bearings and end play on the crankshaft and lack of power, I have just had the entire motor taken down by one of the two best repairmen in Boston, who specializes on overhauling foreign cars, and who does thorough, honest work, from all accounts. He renewed every worn part, refitted all main bearings on the crankshaft that were loose, straightened the crankshaft itself, fitted new camshaft bearings, fitted new piston rings, cleaned out the carbon and ground the valves, and when the motor was assembled and started, I never heard a more silent even-running engine. So much for the condition of the motor.

I have driven about 200 miles since it was overhauled, and the last hundred miles I can feel a distinct thump through the clutch pedal, foot throttle and steering post, whenever the throttle is opened to pick up on a grade and when a load is thrown on the engine. The whole footboard and framework of the car seems to reflect this "knock." It cannot be heard but is quite perceptible to the driver, though passengers have not noticed it. It is a case of feeling and not hearing. Evidently something is loose somewhere and I don't want to pull the whole motor down again if I can avoid it. The repairman thinks that when he adjusted the crankshaft bearings that the alignment between the clutch and transmission may have been changed. Would this cause such a pound? The clutch is housed in the flywheel. This knock is not very severe, but on opening up appears right away. It is not a carbon knock, nor a wrist pin knock, but like a loose main bearing knock, without the noise part of it. When the bearings were renewed, the repairman ran them in under power for a day before assembling. Lubrication has al-

Digitized by Google

ways been good, being force feed. My old car hasn't much power and perhaps I should never attempt to force it, though I am used to a four speed transmission and believe I am easy on a car. Can you throw any light on the case, judging by other cases?

Reply.—There is little doubt in our mind that the thump is a cause of imperfect alignment of the engine crankshaft and transmission, although new transmission bearing bushings may be needed. We consider it just as necessary to assure perfect alignment as to renew bearing bushings, particularly when using cone clutches.

1573 **Length of Sparks.**

From E. E. Edwards, Iowa.—Could I bother the Automobile Dealer and Repairer to ask you for an answer in the March number to the following? We have a 4-cylinder Buick, Model S, and use a timer, a 4-unit non-vibrating coil with master vibrator on end in the same box (a Splitdorf), and get current from a 6-80 storage battery. Now in testing this spring, I find that when I have a cylinder firing I get a good spark at the gap; also that when I short the top of the plug I get a spark ¼ inch or over in length, but I also get a small spark from the other three plugs when shorting them with a hammer from the top of the plug to the top of the cylinder. I have no insulating rubber sleeves on the bottom of the coil on the four secondary tunnels. Would there be enough leakage across to make a faint spark in all plugs? Any suggestions that will aid us will be appreciated.

Reply.—If you will refer to back files of the Automobile Dealer and Repairer you will find that several times we have cautioned owners and operators of motor cars against the all too frequent practice of trying to find how long a spark they can get from their magnetos and coils. You are apparently no exception to the general rule, and if you have not ruined your coils you soon will if you persist in your destructive practice. You should never attempt to run the motor or try the spark unless all the plug wires are attached to the plugs. The plugs do not necessarily have to be in the threaded plug holes, for they can lie on the cylinder tops on their sides, when the spark can be observed, as it ought to be without danger of ruining the coils. You should remember that the secondary current, the electricity which jumps across the spark plug electrodes, may be 500 times the voltage of the ordinary 16 candlepower incandescent electric light, and more than 100 times the voltage used in arc light illumination. It has to have this very high voltage in order to jump a short air gap. If the gap is too long, following the law of least resistance it will go somewhere else quite naturally, and in your case the plug wires being close together it jumps to them and completes the circuit through the other plug gaps. If the other plug wires were sufficiently far apart so the high tension current could not get to them, it would probably jump to the primary winding of the coil and thus burn out the secondary insulation, ruining the coil. The insulating rubber sleeves are not absolutely necessary.

Two Interesting Points.

From J. W. Miller, Lebanon, Kentucky.—I notice No. 1528 is having trouble with oiled spark plugs. This can be easily remedied by tapping out the spark plug holes enough so that the spark plugs will screw one-fourth of an inch further into the firing chamber. I have had the same trouble and know that this is a sure preventive. Of course the plugs must first have the oil cleaned off of them.

If No. 1537, or anyone else with the same trouble—grease working out through brake drums—will drill a one-fourth inch hole in the underside of the axle housing, about six inches from the rear wheel, they will find that the grease will drop out of this hole along the road instead of working out all over the brakes and tires.

How He Avoids Trouble.

From T. J. Preston, Washington.—I have a model T Ford touring car, 1912. I have run it two years, 8,000 miles. I had a master vibrator put on and like it very much and a Prest-o-lite or gas tank. There is just one thing more I want and that is a hand starter, then the Ford will be good enough for me. It is a sure go 365 days in the year. The great trouble with lots of car owners or drivers is that they won't let the adjustment alone. I have not adjusted my carburetor since I got my car, but I keep all wire connections clean and tight. Also the vibrator platinum points clean and smooth. I had 4 dry batteries put in to start on, and they work fine. I had them put in at the same time that I had the master vibrator put on.

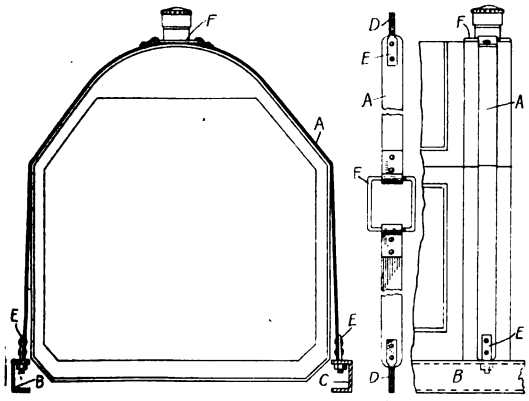
Valve Grinding.

From Wm. A. Amend, Tennessee.—I had my valve seats destroyed by an incompetent repairman and had a continued worry about leaky valves for a long time. The only way that I could overcome this matter was to purchase a set of Tungsten valves, ⅛ larger and reseated the valve seat with a reseater. The valves alone cost me $22. Grind the valves until a white rim extends clear around the valve and seat, then make pencil marks on the valve every ¼ in. Put the valve back accurate but a little piece out. If all the lines are not erased clean then clean the valve and seat well and grind with coal oil. Then lubricate all parts. Use a brace and bit by going forward several times and then reverse. Continue this until the pencil marks erase clean and even. This will make a polished seat, although of course not as good as a ground seat, but it is the best that can be had. The other way of using a valve grinding compound will cut wherever the metal is the softest, whether it be the valve or the valve seat and the longer one grinds the worse will be the seat and the only remedy is a reseater and a valve dresser for the valve.

A Boost for Piston Rings.

From F. H. Ahl, Maryland.—I drive a Cartercar for pleasure, equipped with the American piston rings and my car runs beautifully. My cylinders are like a burnished piece of silver. I do not know what the smoke nuisance is with my car. I have been driving my car for the last two years equipped with the American piston rings. My car is a model S, 1912, weight 3,500 pounds.

For the Leaking Grease.



From J. H. O., Iowa.—If the Ford owners who have trouble with grease working out of the rear axle will take the wheel off on the side that is caus-

Digitized by Google

ing the trouble, remove the cage of roller bearings, then take some strips of cloth two or three inches wide, wrap around the axle, and at the same time keep pushing it in with a small iron rod till the housing is about two-thirds full, not solid, but just what will go in easy, they will find it will remove this trouble. Woolen or old underwear make the best packing. My car was packed in this way two years ago and has caused no trouble since.

Radiator Fastening.

From F. A. Dooley, Nebraska.—I will make a suggestion to Mr. C. Avery of Florida. A very neat looking and the best rigging I know of to tie a radiator, such as he describes, down, is made as follows:

Sketch of the Radiator Fastening.

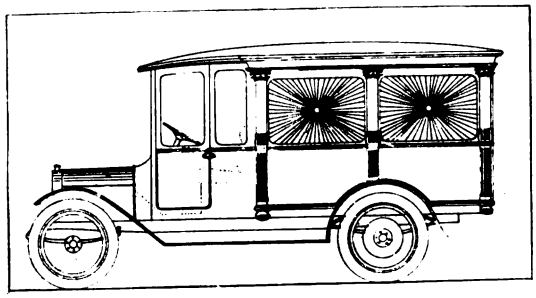
Take a strip of heavy galvanized iron, A, long enough to reach from one side of the car frame, B, up over the top of the radiator down to the other side, C. Cut a hole in the iron to fit over the filler tube. Take two ⅜ inch bolts, D. Cut heads off, flatten out for about 2½ inches, as at E, and rivet one to the lock end of the rigging. Run these bolts through the holes in the frame and screw up the burrs. He must solder the studs back on the bottom of the radiator but must throw the burrs away. If there isn't room on each side of the filler cap to allow enough of the band remaining after cutting the hole, take a ¼ inch iron rod, F, and make an oval or square to fit over the filler tube and rivet the side bands into this, like drawing.

Remedy for Oily Spark Plugs.

From Merle M. Zentz, Nebraska.—In your February issue, under the Trouble Department, No. 1528, in regard to oily spark plugs in a Buick model 17, 1910, I will say that I have had the same trouble in nearly all the older models of Buicks. Personally I have the best success in overcoming this trouble by lowering the oil level in the crank case. I usually do this by simply cutting the dippers off on the lower end of the connecting rods so that they dip into the oil 3/16 or sometimes only ⅛ inch, depending on the seriousness of the trouble. A crank case may be easily measured, both top and bottom by laying a straight edge across and then measuring down to the oil level and also to the end of the dippers. I like this method much better than to cut notches out in the case as I have seen some do, for it is much more easily remedied than is the other in case a mistake is made. Try this once and you will keep up the practice.

Improved Running.

From John Tye, Minnesota.—I own a Ford, model S roadster, 1908. It is still in good running order, I having run it nearly 12,000 miles the last two seasons. I am overhauling it at the present time and expect to run it for another season at least. The only trouble of any consequence that I had with it was the timer. The popping in the carburetor was caused by the nut which fastens the wire being too large, which explodes No. 3 cylinder, and when I advanced the spark it would touch the frames of the engine and cause a short circuit. I filed off a part of the nut and have had no trouble since. I have a magneto attached to my car which runs it fine and saves me on my battery bill. When I first got my car I ran it on batteries altogether and after they had run a while it would miss and did not run very good. Since putting in the magneto and master vibrator it works fine.



Tank Rattle and Plug Leaks.

From M. C. Underhill, New York.—Referring to inquiry No. 1542 by Chas. O. Farrar, Massachusetts, who is troubled with a rattle in his gas tank, the noise is probably caused by one of the baffle plates, which has become loose and is bouncing around inside.

Also tell C. G. Bierbauer, Minnesota, No. 1528, to see that his spark plugs are tight. I also have a model 17 Buick and have been troubled in this way and find that any leak around the spark plugs, or if the valves are not timed correctly, will allow the oil to work into the combustion chamber.

Hearse Bodies for Buick Cars.

In relation to hearse bodies for automobile chassis, it may be stated that the Walker Carriage Co., of Merrimac, Mass., supplies them for Buick and Cadillac cars, but not for the Ford car, as they do

not consider this chassis strong enough for the service. The illustration shows a hearse body fitted to a Buick model C 4 chassis.

That Loose Motor.

From P. G. Liederbach, Minnesota.—I believe the reply to No. 1549 in the February issue is a very reasonable one, although I think the studs were crystalized instead of the flanges of the cylinders. A car that has seen five years service has had a great deal of strain on these studs and although these studs were designed to be of proper size they have lost a great per cent. of their original tensile strength. Sometimes one or two studs will work loose. Should this happen on one side there would be only one stud

Digitized by Google

on that side holding. This could very easily break and with the slack in the other two the block could rock, a condition that the weakened studs could not stand. Although the studs on the other side of the block might be quite tight, the result would be that the flanges of the cylinders would break off very easily by reason of the side strain. I would advise this reader to put in all new studs a thin paper gasket between the cylinders and crankcase, and when putting the cylinders on use washers under the nuts and tighten mighty tight. There is not the ghost of a chance of a crankcase explosion doing this damage, as any explosion in there could not affect the cylinders in the least. The pressure would come against the piston all right, but these are tied to the crankshaft by the connecting rods and the explosion could not reach the cylinders except at the walls and this pressure would be exerted transversely and therefore would not affect the studs.

Battery Ignition Favored.

From P. G. Liederbach, Minnesota.—Much is said these days by magneto makers against battery ignition. They cannot be blamed for this, as that is the means of their livelihood and they feel as though others are encroaching on their business and they must put up a defense.

In the same way the gas light companies are fighting for their business against the electric light companies, claiming their light is the best. The question raised by Dr. Cunningham is that magneto ignition is better than storage battery ignition. I think not. Those who have used battery ignition for several years have no cause for complaint. The rats' nests of wires are on every car that is electrically lighted and started, whether it has a magneto or not. On some cars these wires are ingeniously concealed; on others they are open. They are there just the same. The more they are concealed the harder it is to locate and repair trouble.

To make starting easy, you want a good, fat spark. This you get in battery ignition. If there is any one time that you get a good spark out of a battery that is better than another time it is when the car has been standing with the engine still, and this is just the time a good spark is needed, because the engine is cooled off. We can't crank very fast by hand, neither does a self-starter crank very fast. The gas mixture is, as a rule, not good, by reason of leaks, etc., so we want a fair spark. Do we get this in a magneto? No; if we crank fast we get a fair spark. Dr. Cunningham says the faster the car goes the more intense the spark. If this condition were reversed it would be much better for starting. This is the principal argument against the magneto, because the fat spark comes after the car gets under way.

Nearly all cars now have electric lights and where electric lights are wanted when the engine is still, a storage battery is needed, so the very fact that you have a magneto is not going to save your storage battery expenses. This battery you have to have anyway and the little current you use for ignition, compared with what is used for lighting and starting, is so small that you can hardly figure it at all. I have seen cars where the battery was so low that a hydrometer would not float and still would not miss a shot. If your car has a high tension magneto and this should fail some stormy night when you were a long way from home, what could be done in the dark? There is no other source of ignition. With the battery system, if your battery should fail, switch over on the dry cells and "beat it" home and look for your trouble as you get there.

And then to say that all a magneto needs is an occasional drop of oil, etc. This is putting it very mildly indeed. I have just sent a Splitdorf magneto that has seen three seasons service to the Splitdorf service station at Minneapolis to be put in shape, and the bill was the small sum of $25, and it has had attention from time to time right along. This word "service" surely is catchy and looks harmless, but I think a word could be used in place of it that would be more appropriate, then people would be more careful.

That Jackson Car.

From Joseph Fahey, Connecticut.—I notice in your February issue under the Trouble Department a complaint from Mr. B. H. Prior, Oregon. As I am an owner of an M/35 Jackson I think that I can help him out of his trouble. The engine in this machine is the N. M. & M. Co., and I notice that Mr. Prior has the same trouble that I have had and found that it was all in the carburetor. The Model L Schebler will not fit between the crankcase and engine frame if you leave the old carburetor flange on. This wants to be left off altogether and fit the carburetor properly to the intake manifold. In doing this the holes will not line up properly, so take a rat-tail file and make the holes in the manifold about 1/16 longer and you will have a perfect fit. Then you will have to change the control, as all the new carburetors are built the same way. I had two brackets made to fit over a piece of round steel, 3/8 inch, so that they were adjustable. I made two small brackets to fit the steel on each side of the frame, and run it across the back of the fan bracket.

I also notice that Mr. Prior has tried a 1 inch carburetor. The proper size to fit this car is the 1¼ inch. I have been using the Model L Schebler for about six months in all kinds of weather and it has given perfect satisfaction in every respect, and I am able to throttle the engine down so that it will just turn over. I trust that this information will benefit Mr. Prior.

Motor Indigestion.

From E. S. E., Ohio.—Just a word, please, in response to No. 1533, W. F. K., Indiana, under "Mixture Too Rich" heading. I experienced the same trouble three years ago, and only by very careful study and some experiments, I located the difficulty. Firstly, I would say that the mixture was too rich twice! In the first place it was too rich in quality and secondly it was too rich in quantity. Furthermore, the entire alimentary of his car needs a decidedly violent physic. If the good brother will by carburetor adjustment cut off about 15 to 20 per cent. of his gasoline he will observe quite a difference. Then again, if he will add about a quart of common kerosene oil to his next tankful of gasoline he will observe a greater difference, and yet again, if the next time he runs his motor, while it is still hot, take out number one and number three spark plugs and by aid of a common syringe, squirt about a tablespoonful of kerosene oil over the top of his valves and piston heads and then let it stand

Digitized by Google

still over night before starting his motor, he will discover, by holding a white handkerchief about six inches away from the end of the exhaust pipe, that he has effectually cleansed the machine and both he and his motor will feel a whole lot more like working. To use a term common among the medical fraternity his motor is afflicted with "Pylonic and Intestinal Indigestion," and if it was a human it would be auto-intoxication or self-poisoning. Too much food is decidedly bad for anything. If we eat more than we can easily digest, it will ferment. And a gas engine is a mighty close approach to the human being in this particular respect, besides, such troubles usually have a tendency to disturb the continuity of one's religious intent.

Spark Plug Gaps.

From J. Bonebrake, Indiana.—Some owners of automobiles are frequently buying new spark plugs. They come to me to fix their old ones. I have run a Ford car nearly seven years but do not even think of spark plug trouble. I set the gap of my plugs just wide enough to take a thin dime and make each gap absolutely the same. If any one has a better remedy than this for spark plug trouble I would like to know it.

An Easy Constructed Turntable.

This turntable will be found not only useful in a garage, but simple in its construction. In Fig. 1, the top of table A, is made by crossing 6 inch planks, as

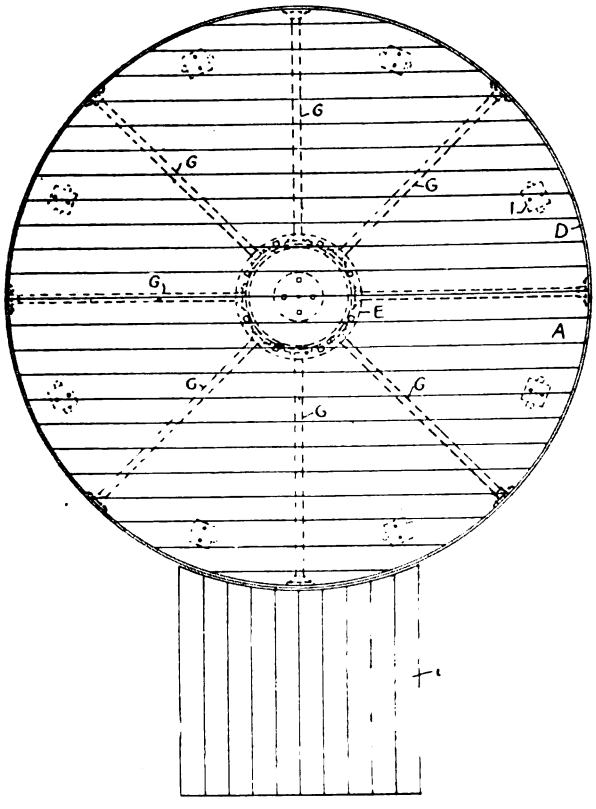


Fig. 1.

better shown in Fig. 2, at B and C. On the edges is an iron hoop D, to preserve the edges of the timber. At E we have an angle iron hoop, as well as at F. At G is a 1¼ inch pipe, with ordinary floor rail sockets H, which in turn are bolted to hoops E and F, and act as a brace for the top of the table. We have at I, ordinary truck rollers which ride in an L shape iron runner. K is the pivot on which the turntable revolves. This turntable is built up above the floor to do away with the expense of the con-

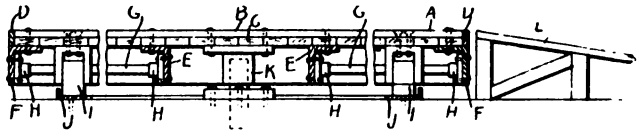

Fig. 2.

struction of a pit to receive the turntable, and therefore it is necessary for a runboard, shown at L, in Fig. 1 and Fig. 2.

TIRE EXPENSE.

Care and Attention Necessary to Their Proper Wear and Service.

From D. H. B., New York.—The question of tire expense has always been a serious one for the motorist. But when tires receive the care and attention which they should have, tire expense will cease to be an impediment to the enjoyment of motoring. Many drivers have little or no regard for the life of their tires, trusting mostly to luck to carry them through.

Often the life of a tire is shortened by being applied to the wheel so that it is out of alignment. This tends to wear the tread unevenly and soon disables the tire. A little care in applying, to see that the tire is even all around the rim, will save many dollars for the owner. I have personally seen a man using a common hammer in removing a tire, and he was pounding the sides of the tire with all his strength. Of course, he succeeded in getting the tire off—but at what cost? Certainly he bruised the rubber and fabric and laid an excellent foundation for a quick blowout. A little patience and the proper tools would have been more efficient and left several hundred miles of added service in the tire.

Furthermore, many persons carry their extra tires without any covering or protection whatever, exposing the rubber to the deteriorating elements of light, heat, dust, water and the sun's rays, and when they have need for this tire it has become partially baked and the real rubber-life far spent. Another point to consider is the care of tires when the car is to remain idle for a considerable period. It is a conceded fact that if tires are permitted to sustain the dead weight of a car for a long time, they will become sufficiently flattened at the points of contact with the floor to pound the tread loose when they are put into service again. Then, too, it frequently happens that the garage floor is damp, and if tires remain on a damp floor the fabric will absorb the dampness and become greatly weakened. This is one of the many causes which starts the process of tread separation. The remedy is simple—jack the car up each time it is brought into the garage.

A man has the right to expect "service" from a tire, provided he purchases a high-grade one, but he must be willing to take reasonable care of his tire if he would receive "extra service." The use of chains will materially shorten a tire's life, and they should be employed only when absolutely necessary and removed immediately they are no longer needed. But how many put chains on for a rainy day and

Digitized by Google

permit them to remain for a week, even though the roads have long since become dry?

In using chains the cross-members should always have plenty of play to distribute the wear on the tire.

Some people claim to have been fortunate in the use of "second" tires. While some "seconds" wear well, from my experience I believe that in the end they are more expensive than "firsts." This may be a matter of opinion, but I have seen a tire which cost $27 and which after a few hundred miles of service was utterly ruined by a six-inch blowout along the bead, and the owner had absolutely no redress. This is only one case. I could cite many more.

It is no doubt a fact that more tires are ruined through under-inflation than from all other causes combined. If one would keep his tires inflated to a pressure of eighteen or twenty pounds to every inch of cross-section of the tire, he would be quite free from blowouts. Even during the hot weather this pressure should be maintained, as it has been conclusively proven that the extra pressure caused by friction is so small, it need not be considered. But care must be taken to see that the tubes are of the best quality, for in reality the tube is the "heart" of the tire. Red tubes seem to give the best satisfaction and will withstand the heat exceptionally well.

Tires well inflated add to the efficiency of the car, for it takes less power to operate the car when the tires are hard. Tires properly inflated also have much less tendency toward sidewise distortion, when there is a severe strain on the tire bead.

As an illustration of a case where proper inflation was entirely disregarded, a man stated to me that his tires (3½ inch) couldn't very well blowout, as he only kept thirty-five pounds pressure in them. He was defeating the very object which he sought to overcome—for he had just half enough in his tires.

To-day tire construction receives as much scientific consideration as the car itself, and with proper care and intelligent use there is no reason why tires should continue to be a source of great expense to the car owner.

NOW A WAR ZONE.

Notes of an Automobile Trip in a Land Now Devastated by Conflict.

From Felix J. Koch, Ohio.—When Europe settles down to its normal self once more, go try for yourself and be convinced. If you can find a more delightful bit of touring than that from Banjaluka to Rjeka—"Jacje" it is pronounced—in the Balkans, over as good a road, among as quaint a people and in a land where government hotels are as cheap and as good, we'll take off our hats to you, proceed thence, and say thank you, at end.

To begin with, when Austria-Hungary built those roads down in Bosnia she was being put on her mettle. Austria-Hungary was given permission by the Powers to occupy Bosnia, after the upset of the '70s, and realizing that what would start as a temporary occupation would mean actual acquisition as soon as the folk down there acquiesced, she proceeded to give Bosnia the world's model government, until Uncle Sam tried to imitate on the Isthmus of Panama. So you have roads winding through the mountains and crossing the streams and scaling the heights by easy stages. Well, when we say that we even let Roosa drive the machine on those hills, you can guess how good the roads must be.

Then again, Austria knew that to advertise you must get people to come down and see, so she opened hotels of her own, established rates and tariffs and to-day you can get more for a shilling or a quarter in Bosnia than two dollars and fifty cents will give you in a New York hotel. That, though, is just incidental to the actual tale of the touring.

To save time we had the machine shipped from Fiume, where we landed, to Banjaluka, where we really struck Bosnia. Thence we entered what is to-day the real war zone, the last real news from there being that Montenegrin troops were swarming over the land. We stopped at night at Bajaluka and we'll never forget the charm of it. Then next morning we went on to explore, first the environs of the city, then out that road which leads, not straight as an arrow, but by mildest ascent and gradient, through those wonderful Balkan canyons to the other town. Every foot of the way had its interest.

Well Loaded.

Roosa had just paid the hotel bill and he was radiant. "Think of it, $1.20 each for that room for three nights; that big room and everything a man might desire."

Roosa paid for the gasoline at the garage, careless of what it cost; the saving on what he expected to spend for hotels would more than equalize. In a merry mood, therefore, we started out.

The way led past the little shops of the Moslem inhabitants—the Turks—people call them, though they are no longer Turkish subjects and haven't been since Austria made her occupation some half-dozen years or so since. The shops are of one story. At front there is a great open window, down from whose upper sash the prize wares suspend. At the store front is a counter, and around the sides shelves hold wares, visible to all from the street side. And so we jogged along slowly and we stopped to buy what we would. That is the charm of motoring in bazaar-lands; you buy from your auto and pile in the machine and go on as you choose.

People walk in the street itself, in most of these countries, and strange folk very often they were. Once it would be a Serb priest in a long black robe, black fez, long black beard, crossing squarely, and Roosa would snapshot him as he went. Again it was Turkish women, dressed in black gowns, their

Digitized by Google

heads swathed in windings of white linen. You never so much as address a Moslem woman in the Balkans, so Roosa got those pictures on the sly. Meanwhile we noted how those swathings about the heads of the damsels were folded so that a slat, or eave, permitted them to look on the walk as they went.

As we reached the outskirts we took on speed,

Watching Us Pass.

naturally. When a Turkish hodja, or priest, in splendid white turban and gown, crossed ahead, Roosa hardly dared toot the horn and order him out. It pays to respect Islam when traveling in Bosnia. Other men, we found, on this roadway wear the turban throughout, preferring it to the fez, as being warmer for use in the uplands. Only the hadjis, or pilgrims, who had been to Mecca might have beards, per the faith, and so we commented on these all but smooth-shaven men as we passed. Most men had a moustache, but not all of them.

The Coffee House.

Only certain classes, we soon learned, might wear green turbans here.

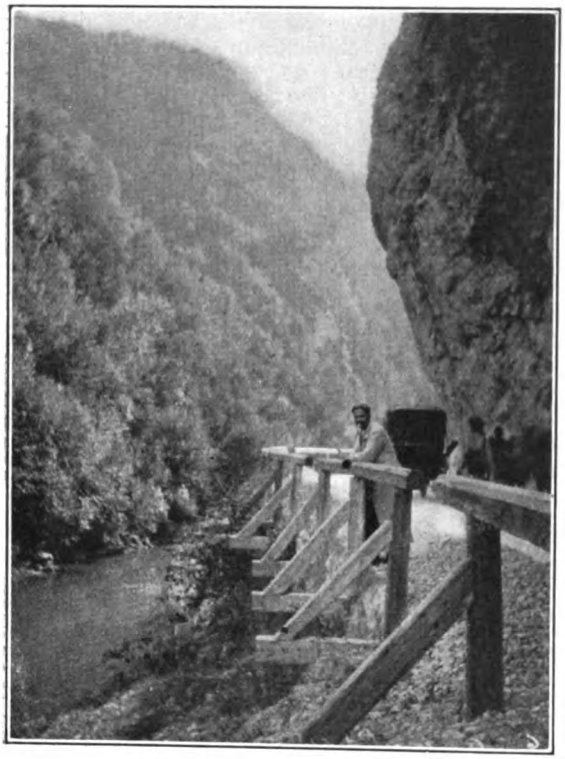
The speed that we traveled at means nothing. We'd hardly come out of low, after stalling abruptly, before Roosa stopped short once more for a snapshot on the way. The women sauntering townward, in their clog shoes, detained him; three Bosnian Christian peasants a-horse, each with red fez, white shirt and sleeveless coat of sheepskin.

At last we got well on our way into the mountains, their slopes well cultivated though wearing few trees. Here there was magnificent scenery; there were brooks and cascades and serpentines of roads. But more than all, there were wayfarers to attract us. Again and again we slowed up and went slowly to side while Bosnians quarreled with the donkeys they straddled, to get them to give us the way. Sometimes the peasants walked beside them and were likewise stubborn and we had to bide our time to get by. In due course we passed through a settlement, old two-story frame huts, with verandas along their second floor and a bazaar in the corner room of the first story. Turks were in charge of all and they hardly gave us a look as we passed. On beyond splendid plums were ripe at the roadside, or hung from branches protruding over the walls to the pastures, each side the pike. As we nibbled stolen sweets there, we traveled onward until Turkish homes, some of great size, their second-floor windows latticed, the first floor on a level with the wall built round the yard and so invisible to us, came to

A Devotee of Islam.

hand. Along the right, a creek ran all the way at a good rate, rippling around the feet of the mountains, but well curbed off the road.

Now and then some Jewish trader would be encountered, his cart laden; shrewd at his bargains and so disliked, yet patronized, for he did sell things cheap to all. Then more homes, plaster-coated, wider on second story than first, put in appearance. From these we rounded to a cemetery at the foot of the slopes. Turbans grace the headstones of the men in the Moslem graveyards. The stones for women are plain; often there is no stone and there is no casket at all. On our right and left the Balkan mountains grew higher. Stupendous peaks and crags began hemming us in. Forty years ago who went through here did so at his peril; to-day it was so safe we might have stopped for a "blow out," and a thousand inquisitive peasants gathered round to look on, yet not one untoward incident would occur.



Corn fields, plum orchards, yielding the prune for the "slivowitz." Then mountain forests, dense, impenetrable right side and left. At their feet our brook, now a very blue river, with cascades and riffles to make it sing and then roar. Sometimes goats in numbers, or cows, would be seen on the foothills. Again, donkeys, with panniers laden with pears, would rest next some telephone post at the roadside.

We had exhausted the film we had handy and

Digitized by Google

Roosa wanted to get at our trunk back behind. Nestling at the roadside was an inn. Its white plaster-house walls bespeaking a clean hospitality within.

If you have ever traveled the Orient you know how irresistible the inns are. You stop for Turkish coffee at each of them, and you halt as much to chat with the old, turbaned Moslem who has the place in charge. Roosa stalled—I vow he did it on purpose—then, before we could question, he had shut off the gas. By that time, bearded Islam was out upon us. He had the usual tray, with its two tiny, round saucers of white porcelain, with pattern in red and blue. Into these saucers—bowletts perhaps are better—(they had no handles and so were not cups)

Some Scenery.

went the strong Turkish coffee, which one drinks without milk always. As we halted the Turk poured more coffee from his small, brass, sharp-mouthed canister into two more cups, the sugar already in. As the mass melted and sweetened, we drank of the other. Then he brought ice-cold water to wash down the grains, for in Turkey the coffee is ground fine as powder and you really drink grounds, thus, and all. Furthermore, the water settled the bits of caffine on the palate and you get an after-taste that lingers till the next stop.

Naturally, Roosa must have a second order of coffee; it is but two cents a cup, so who would object. Our host invited us to the summer-house across the road. We could only enter, however, when a Moslem woman, already there, had retired. Then Roosa posed him for pictures and posed native guests in the meal room. We lost half an hour at least in the place.

Only then did we launch anew for Rjeka. A long ride, a fascinating one, still, in prospect. But what matter, whether we got in at dusk, or at sunset, or by moonlight, who cared? We were out to see things, to enjoy the wonderful touring. We could never rely on memory or note-books to bring it back. Long after our tour we could enjoy those pictures. So we pardoned Roosa the delays he had occasioned again and again.

To-day, in fact, every time we look over the collection we get a fresh hankering to tour downtown there once more. Things may be a bit primitive; you may miss some things you are accustomed to, but in our opinion this nook of the Balkans, is the motorist's happy hunting-ground of the world.

THAT NEW GASOLINE.

Much Is Promised But It Does Not Disturb the Standard Oil Company.

Secretary of the Interior Lane has announced the discovery by the United States Bureau of Mines of two chemical processes, one of which, it is claimed, will be of much importance to the oil industry, greatly increasing the supply of gasoline, while the other may make the United States independent of the rest of the world in regard to important materials necessary for the dye industry and the manufacture of high explosives used in warfare and in engineering operations.

The first of these processes it is claimed will enable the independent refiners in this country to increase their output of gasoline from petroleum 200 per cent. or more. With an estimated production on the part of the independent refiners of 12,000,000 barrels of gasoline in a year, this will mean an output from the independents alone of 36,000,000 barrels, greater than the total production to-day from all sources.

The second process includes the manufacture from crude petroleum of what is known chemically as toluol and benzol, both of which have heretofore been obtained from coal tar. As Germany has specialized far beyond other countries in by-products from coal, the United States and the rest of the world have been dominated by that country as regards those products of toluol and benzol which are the important bases for the production of dye stuffs and high explosives, and especially smokeless powder.

The discoverer of these two processes, after many years of research, is Dr. Walter F. Rittman, chemical engineer of the Bureau of Mines, the work having been done at Columbia University, New York, the facilities of the laboratory there having been turned over to the Federal Government by President Nicholas Murray Butler.

Application has been made by Dr. Rittman, on behalf of the Federal Government, to patent these processes in order to prevent any monopoly in their use, the patents to be dedicated to the whole American people.

"These processes," said Secretary Lane to-day, "are fraught with the utmost importance to the people of this country. For some time the Standard Oil Company, through the great amount of money at its command, through its employment of expert chemists and through its extensive organization, has had a big advantage over the independents in the production of gasoline, this company having a patented process that obtains for it as much as three times the amount of gasoline from a given

Digitized by Google

quantity of petroleum as the independents now obtain. There are two or three other large corporations that have an efficient process for the manufacture of gasoline, but the independents as a whole have never been able even to approach the results obtained by the Standard Oil Company. Now the Federal Government, through the efforts of Dr. Rittman, proposes to make free for the use of all of the people of this country who wish it, a process that is confidently expected to increase their yields of gasoline from crude petroleum fully 200 per cent. and perhaps more, such results having repeatedly been obtained in the laboratory. It is claimed by Dr. Rittman that his process is safer, simpler and is more economical in time than processes now in use and these are economic factors of great importance. With a steadily increasing demand for gasoline for automobiles, motor boats and engines, this fortunate discovery comes at the proper time. It is but two years ago that the automobile industry, fearful that the supply of gasoline might not be adequate for its rapidly expanding business, offered through the International Association of Recognized Automobile Clubs, a prize of $100,000 for a substitute for gasoline that would cost less than gasoline. Happily the urgency of this situation has passed and at the present time there is a plentiful supply of motor fuel to meet the immediate demand. This new process adds to the hope, that in spite of the wonderful growth in the use of gasoline, there may not be any shortage in the future. It indicates an increased production of gasoline from the present production of petroleum—an output of 50,000,000 barrels instead of 25,000,000, as under the present methods. It will render free for use to all, the results of that efficient and intelligent research which has heretofore been only at the command of the wealthy. I am led to believe that it will not only be of inestimable value to the refiners commanding but limited capital as well as those of wealth, but also to the hundreds of thousands of users of gasoline. When it is realized that the gasoline industry each year in this country yields products amounting in value to between $100,000,000 and $150,000,000, the importance of this discovery is seen."

In relation to this matter, a Standard Oil official has stated that their company has not taken the announcement of the new fuel seriously, although it is admitted that nothing is known of Dr. Rittman's discoveries. The company took the attitude that if the patents were given to the public it would be able to use them as well as anyone else.

The Standard Oil Company also pointed out that benzol and toluol can be produced from very few crude oils and that millions of pounds of coal tar products are yearly burned under coke ovens, and that these products could be utilized in producing benzol and toluol if it were not cheaper to buy them from Germany. No allowance, however, was made for the fact that Dr. Rittman's new method might make the cost of manufacture so low that it would be cheaper to make these products than to import them from Europe.

The slightest escape of current will quickly run down a dry cell. Moisture in the paper covers, occasional touching of metal to the zinc binding post, incomplete opening of the switch, and too much testing with an electric meter, are all prolific sources of no current.

A Work Bench for the Garage.

This work bench is constructed entirely of angle iron, and also has a metal top made of sheet iron, A, as shown in Fig. 2. On one end, as shown at B, Fig. 1, is four drawers to keep tools, etc., in, and will be found very useful in a bench of this kind.

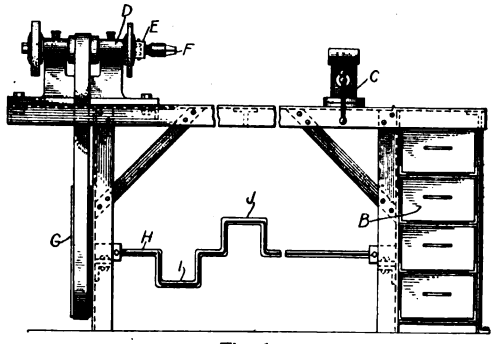


Fig. 1.

There is also a vise, C, to hold the work in as this is useful in many cases of repairing. At D, is an ordinary emery stand which can be used as a speed lathe by boring a hole in the nut, E, and fastened to it is a chuck, F. This can be used for filing pins and for

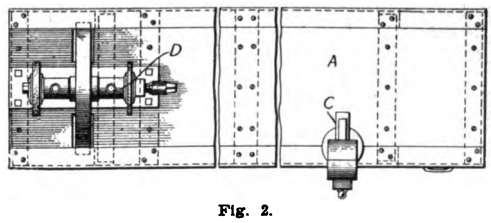

Fig. 2.

a number of small jobs that have to be done on a regular speed lathe. You can also use a circular brush in the chuck for cleaning bearings, etc. The emery stand is operated by a large belt pulley, G. The pulley, G, is mounted on a shaft, H, which is

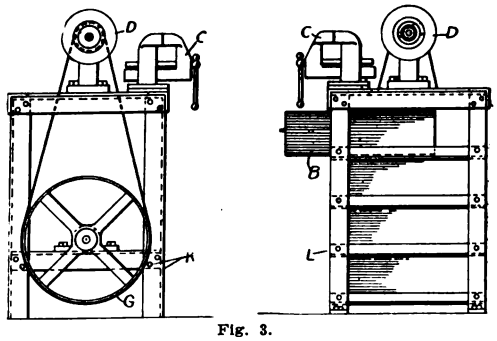

Fig. 3.

shaped as shown in Fig. 1, with foot pedals I and J. In Fig. 3, at E, is an end view of the bench showing pulley, G, and construction of the bench. At L, Fig. 3, is also an end view showing the drawers and construction of the bench. This work bench is 8 feet long and 2 feet wide by 2 feet 6 inches high.

There are three principal points of lubrication in the Ford car that should receive special care. The crank case supply, the universal joint and the differential gears.

EIGHT CYLINDERS DISCUSSED.

Indiana Engineers Differ in Their Opinions as to Their Merits.

Eight cylinder motors were discussed at length in the regular meeting of the Indiana Section of the Society of Automobile Engineers last month, in Indianapolis. The speaker of the evening was J. O. Heinze, chief engineer of the Northway Motor & Mfg. Co., of Detroit. The central theme of his discourse was that "the nearer we approximate the turbine in smoothness of action the closer we are to the ultimate or ideal condition." He reviewed the problems of the eight, reciting its difficult manufacturing points rather than elucidating its most desirable points. The particular advantages of the eight which he pointed out were its unparalleled smoothness of operation which made the wear and tear on the parts less than on a motor of fewer cylinders. Its ability to accelerate better and to require less gear changing were cited as further advantages. Among the problems that arose in its design were proper lubrication without overdoing it, forked versus single connecting rods, accessibility, ease of repairing, adjustment of bearings, manufacturing cost, camshafts and valve timing, carburetion and efficiency.

The discussion that followed the paper was opened by W. G. Wall, chief engineer of the National Motor Vehicle Co. He pointed out that the eight of the same displacement as that of a four or a six-cylinder motor had much more rubbing surface in the pistons. He said that the eight had 40 per cent. more than a four and 17 per cent. more than a six of the same displacement. He built and gave up the eight-cylinder motor in 1909 because of expense of manufacturing such a design. He also pointed out that vertical vibrations in the chassis were not so objectionable as the sidewise ones of the eight.

Howard Marmon, chief engineer of the Nordyke & Marmon Co., gave an opinon that the eight was a psychological proposition rather than an engineering one and that what the public thought of it a year from now would be the criterion of its success. He pointed out that one could not tell the difference in vibration between well-built four, six or eight-cylinder motors to-day under ordinary running speeds. It was only down around three or four miles an hour that you could distinguish the difference between them, so he affirmed.

Elmer Apperson wanted to know how one takes up the wear in the forked connecting rods. Heinze explained that the angular motion of the outside rod was only 12 degrees in their motor and the wear was much like that on a wrist or piston pin. Paul Grimes, of the Wheeler & Schebler Co., said that George Schebler built a twelve-cylinder automobile motor in 1908 and drove it for three years. He then put it in a motor boat and is now building another.

George Weidely, former chief engineer of the Premier Motor Mfg. Co., pointed out that the six and the eight had about the same smoothness of torque and that the former was much more economical than the latter. Heinze had said in the discussion previously that smoothness, long life of motor parts, and little gear changing were more desirable than economy. Weidely suggested that if the public were not interested in economy, why were the results of economy trials on the speedway and elsewhere so interesting to them? O'Neil, of the Stromberg company said that his company had an eight-cylinder motor and had been making extensive tests with a view to adapting Stromberg carburetors for eight-cylinder motors.

A remark had been made by some one that valves placed at an angle would give trouble. Sargent, of the Lyons-Atlas, refuted this at once. He said that he had used valves as large as 16 inches in diameter at an angle without trouble. He added that if they tended to give trouble they used a flat seat instead of 45 degree one.

John Guy Monihan, of the Mutual Motors Co., gave a note on the psychology of the proposition. "Is one's social status going to be measured by the number of cylinders?" he asked. "We have only a few drays with the one and two-cylinders to-day," he jocundly remarked, "so now will the city man have to settle the difference with an eight or a twelve?"

George Dickson, of the National Motor Vehicle Co., when called upon said that so far they had not had any public call for an eight. Chas. S. Crawford, chief engineer of the Cole Motor Car Co., cited the fact that the number of inquiries depended upon whether you were prepared to furnish an eight or not and that from his point of view there was a decided demand for eights. Chester S. Ricker remarked that even horizontal valves such as had been used on the Lanchester cars in England for fifteen years did not give any great amount of trouble on account of their position. Heinze, when asked the relative efficiency of the four and eight-cylinder motors of the same displacement said that no absolutely accurate tests had been made by him yet, but that in one case some rough tests with two similar chassis having about the same weight and equipped one with a four-cylinder motor and the other with an eight made twelve and ten and a half miles per gallon respectively.

The question of ignition arose and Heinze said only Atwater Kent and Delco battery ignition systems were used at the present time, but he expected to see magnetos made that would work on an eight-cylinder motor.

Light at Night.

The only light that is useful in automobile driving at night is that which is thrown on the roadway. This effect may be obtained by painting the lower segment of the conical reflector and letting the rays that strike the upper part and are directed downward do all the lighting.

A simple method of avoiding the objectionable glare is to direct the light downward by bending the lamp supports so that the principal rays will strike the roadway about fifty feet ahead of the car.

It is a mistake to increase the power of an engine beyond the amount for which it was designed, no matter what means may be used. By so doing there is placed upon the working parts of both engine and chassis an excessive strain that may injure the whole car.

The contact points of the coils on the Ford car are of more than usual endurance yet they will pit after long use and require smoothing with a fine file to restore even running of the motor.

Coming Events.

Springfield, Mass., March 22 to 27.—Automobile Show, the Auditorium; managers, Graham & Hobbs.

Mason City, Ia., March 25 to 27.—Automobile Show, the Armory; manager, Mason City Automobile Dealers' Association.

Oklahoma City, Okla., April 20 to 22.—Road race; manager, South Western Automobile Racing Association.

Boston, Mass., May 18 and 19.—Annual meeting of the American Automobile Association.

Indianapolis, Ind., May 29.—International sweepstakes; manager, Indianapolis Motor Speedway.

Galesburg, Ill., June 16.—200-mile race; manager, Galesburg District Fair.

Chicago, Ill., June 19.—500-mile race; manager, Chicago Motor Speedway.

Sioux City, Ia., June 25.—300-mile race; manager, Sioux City Speedway Association.

Sioux City, Ia., July 3.—300-mile race; manager, Sioux City Speedway Association.

Tacoma, Wash., July 4.—Speedway races; manager, Tacoma Speedway Association.

Visalia, Cal., July 4.—Road race; manager, Tulare County Automobile Association.

Omaha, Neb., July 5.—Speedway races; manager, Omaha Motor Speedway.

Burlington, Ia., July 9.—100-mile track race; manager, Tri-State Fair Association.

Denver, Colo., July 31.—Road race; manager, Chas. L. Newcomb, Jr.

Janesville, Wis., August 14.—Track meet; manager, Janesville Park Association.

Elgin, Ill., August 20 and 21.—Elgin road races; manager, Chicago Automobile Club.

A Simple Ratchet Wrench.

A ratchet wrench has been demonstrated as being the best and quickest way to tighten and loosen nuts.

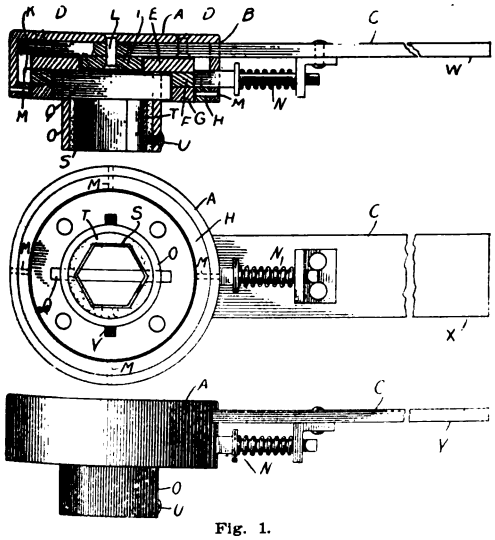

Fig. 1.

This design is simple and can receive nuts from ¾ inch to ⅜ inch or more. The construction consists of a 2½ inch pipe cap A, Fig. 1, with an opening cut at B, to permit the handle C to enter into and is held in position by rivets D. Then take five washers E, F, G, H, I, and drill holes J, in the washers E, G, F, as shown in Fig. 2. Rivet the washers together as one. F is the ratchet washer and is notched with a chisel as at K, Fig. 1, and Fig. 2. Washer I, is held in place by the rivet L, and is used as a center for washers E, G, and F, as well as the guide washer F, which is held in place by pins M. The catch N, is to engage in the notches K, to turn E, G, and F, by

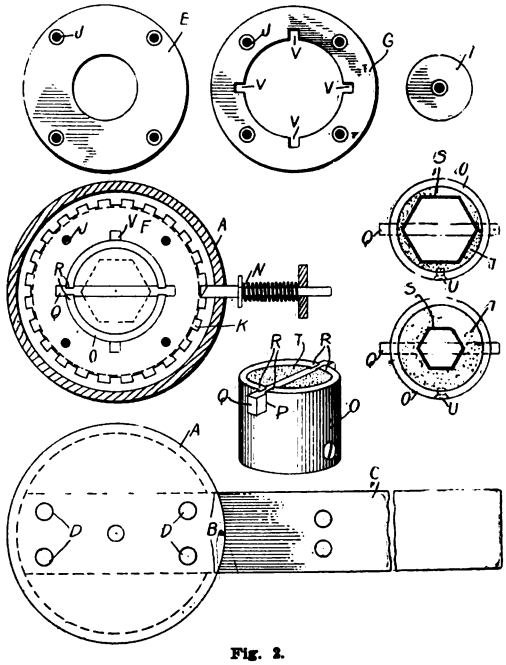

Fig. 2.

pulling forward on the handle C. Now take a 1¼ inch pipe O, and cut off as many pieces as needed for the size nuts and cut two notches P, Fig. 2, to receive a bar Q, and turn the edges over as at R, to hold the bar tight. Then take a piece of thin metal S, and form it, as shown in Fig. 2, on the different size nuts, and place it in the pipe. When this is accomplished pour melted babbitt or lead around it as at T, which is held in place by the screw U. Washers G and F have a recess to receive bar A. This ratchet wrench can reverse by reversing the catch N. In Fig. 1, at W, is a sectional view. X is the bottom view. Y is a side view and Fig. 2 shows detail parts.

Vulcanizing a Patch.

Several vulcanizations, one over the other, will make a better wearing patch, allowing plenty of time between them. Common gasoline now contains some grease, and a higher grade should be used for cleaning the rubber. The casing should be left on the demountable rim and fully pumped up when vulcanized.

To secure uniformity of solution the water and acid should be well mixed before pouring it into the battery cells. In mixing, the water should be placed in a porcelain or enamel ware dish and the acid added slowly, stirring continuously with a clean wood paddle. Mixing causes the mixture to become quite warm, and the solution should not be placed in the cells until it has cooled down.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

ANOTHER WARNING.

Swindling subscription agents have found it profitable to solicit subscriptions for the Automobile Dealer and Repairer and doubtless many other publications throughout the country, putting the money collected in their pockets and never reporting anything to the publishers. There are several of these rascals now working around in different parts of the country. Sometimes, we have been informed, they have receipts printed to imitate the receipts of the various publishers so as to more easily deceive those they approach for a subscription.

Prospective subscribers are warned to pay no money to any man who cannot show an authorization signed by the president of this company and written on the letter head of this office. Regular subscribers, of course, send their subscriptions direct to us always as we allow no commission on renewals of subscriptions. If any reader is approached by one of these swindlers we hope he will kindly give us a description of the man, that is, as to his height, weight, age, color of eyes, whether light complexion or dark, color of hair, whether clean shaven or wearing beard of any kind and how dressed. We want to get on the track of these swindlers and put them where they belong.

THE DECEIVING EYE.

Car drivers should be aware—and many of them are aware—that there is none of the five senses so deceptive as the eye. For illustration, the eye often conveys the feeling that the automobile is going up-grade when it is really going down-grade, or down-grade when it is really going up-grade. One may be ascending a very steep hill indeed when seemingly there is but a slight rise, or he may be ascending a seemingly slight rise and wonder why his engine labors so strenuously in negotiating it.

We know of no reason for this anomalous situation or deception unless it be the grades of the surrounding country. For instance, it is possible that if there chances to be a steeper grade adjoining the road, the grade which the car is making may seem less by comparison. At all events, we know of no other reason to account for it, but if any reader has a different hypothesis we should be glad to know what it is.

But the eye is often otherwise deceptive in instances which are not so easily accounted for. Possibly some of our readers may have sat on the grand stand at a baseball game—assuming that they enjoy this pastime—when right beside them is an individual who claims that the base runner is "out at first," or other base, as the case may be. Yet to him the runner seems clearly not out. Now each is equally honest and sincere in expressing what his own eyes tell him, and it would be hardly fair to assume that prejudice accounts for the difference of opinion or feeling. It is largely due to deceiving vision.

Or one may be seated in a railway coach while passing a small body of water in a hilly country. Of course the water must be absolutely level, but does it often seem so? Or in the case of a running stream, does it not frequently seem as if the current were running up-hill, so to speak?

Interested readers may be able to throw some light upon this subject of deceptive vision, which is most important in relation to automobile driving.

SECOND-HAND CARS.

Occasionally letters are received asking advice as to the purchase of second-hand cars. Buying a second-hand car is like buying anything else that is second-hand. If it is absolutely what the intending purchaser wants, and he is sure of the amount and kind of usage it has had, he is likely to get a good bargain.

But the conditions surrounding all second-hand articles are not as favorable as new ones. If a man is looking for a new car he can easily find anything that is on the market, and he thus has a wide range for choice. He can get the kind, the model of the kind, or a choice of several kinds. He can also inspect them at his leisure, which he can likewise do in the case of a second-hand car unless it is sold at auction, when of course he is probably obliged to examine quickly and bid quickly. Quite likely the second-hand car is not absolutely what the intending purchaser would choose, but the chances are that he must take that one or no other. It is thus often a question of how much one is willing to sacrifice in personal choice for the privilege of a lower price.

Second-hand cars are not usually quite up-to-date, whether they are offered at private sale or at auction. This fact must be admitted unless it be assumed that the automobile art is not progressive, which would not be strictly correct. There is not yet and will not be for years to come, anything like the standardization of automobiles. There are too many different viewpoints, too many problems of engineering, too much to be learned concerning use

Digitized by Google

and stress. If manufacturers do not learn something concerning construction or material from year to year, then they lack business ability and will soon fall behind the procession. It is true, the improvement may be slight, but in detail it ought to be something every year and for a good many years to come.

In the case of a vehicle that must carry its own power of propulsion, and that is driven with the speed of a railway train, there are problems of engineering and of construction that possibly may not have their match in any other piece of machinery made.

NEITHER PRACTICAL NOR ETHICAL.

Not content with robbing the railroads by its refusal to increase their compensation after the Parcel Post system was introduced, the Government later issued an order extending the service to packages of large size and increased weight, thereby depriving the railroads of carrying freight at a legitimate rate.

The Parcel Post was heralded as a great money-making proposition, and it ought to be, in view of the fact that all parcels are carried far less than cost, yet it appears that the Post Office Department is running behind and there is a suspicion that the Parcel Post is responsible for it.

Postmaster-General Hitchcock before his retirement, and when the Parcel Post was first inaugurated, introduced a system of special stamps with the laudable purpose of determining the exact cost of carrying packages. As the rates fixed were mere guesswork, the Government did not know whether it could afford to carry packages at present rates or not. It was therefore good business to try and find out about it.

The present Postmaster-General, unwisely it is believed, abolished the special stamps, and of course the department is now all at sea as to the real cost of the Parcel Post to this department. There is no possible way, under existing conditions, to solve the problem of such rates.

If a private corporation were conducted with a similar disregard, not only of business principles, but of justice as it concerns payment to the railroads for a stated service, it would either soon land in bankruptcy or achieve an unenviable reputation for business ethics.

A PECULIAR MANDATE.

An instance of somewhat fine distinction has recently come up in Peoria, Ill. It appears that the Ford Motor Company has compelled a garage owner of that city to change the name of his firm from Ford Repair Shop to some other name less suggestive of official Ford connection. The garage owner selected the name "The Repair Shop for Ford Cars"—but it is still doubtful whether this slight change will be found satisfactory from the point of view of the Ford Motor Company.

The accredited representatives of the Ford Company in Peoria contend that the use of the name Ford has caused them annoyance and loss of customers, and has led the public to believe that there are two Ford establishments in Peoria. Replacement parts and accessories carried by the Ford agents are said to have suffered in a cut-price war, and repairs have been carried out in a manner not agreeable to the Ford agent.

What kind of a new principle in law is this, anyway? Surely, any one whoever has a right to repair Ford cars, whether he is the agent for them or not, and having that right, he undoubtedly has the right to say that he does it, and either publicly or privately, as he prefers.

It will be interesting to learn what kind of a court of justice "compelled" the Ford repair man to change his sign as stated above.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

The accounts of accidents received this month, as clipped from the newspapers, are largely what may be termed winter month accidents. That is, many of them were due to slippery roads and streets. In most cases of this sort they are not serious, for when the roads are known to be slippery most drivers naturally proceed with additional care, so if an accident does occur it is not liable to be as destructive as if the car were going at high speed. Some of the following are of the more unusual sort and it is hoped they will be a warning to careless drivers. Lack of space only makes the list a short one.

One Dead and Three Injured.—In Perry, Mo., a party of young people, who were riding in an automobile, overturned on a straight and fairly good road. The car was rapidly going down a slight grade and it must have hit a rut in the road or some obstruction. It swerved and immediately overturned. One young woman was killed and three others suffered broken bones and bad bruises.

Due to a Dog.—Near St. Louis, Mo., in attempting to avoid striking a dog that crossed in front of a car, it struck a curb and three of the occupants were pinned beneath it when it overturned. One was killed and three were seriously hurt. The valuable touring car was completely wrecked.

Plunges into a Gulch.—Two men were killed and two injured near Tacoma, Wash., when the automobile in which they were riding plunged 40 feet into a gulch below. There was a turn just before the bridge was reached and the driver attempted to make it without slacking his speed. The occupants were all thrown clear of the car as it began its fatal leap. It is stated that the driver had the appearance of being intoxicated, but he claims this is untrue. He asserts that his car was not traveling more than four miles an hour, while others claim it was going four times that speed.

Plunges into a Car.—Going at a lively speed from New York to Philadelphia, a man with his wife, son and chauffeur plunged into a crowd of high school girls near Trenton, N. J., and some of them were seriously injured. There was carelessness somewhere and judging from reports the chauffeur was to blame. When a body of high school girls, or any other girls, get to talking they are not likely to notice what is going on before them.

Dozing at the Wheel.—Near Taft, Fla., a young man left his father's home at a late hour to carry several of his friends to their homes. He then

Digitized by Google

started to go on to Orlando where he was engaged in the motor livery business. His ride had been a long one and he may have been dozing while driving. In some manner he grasped the clutch and gave the wheel a quick turn, thinking he had reached an abrupt curve to which the machine was approaching. The car completely turned over pinning the young man beneath. It is likely that his death was instantaneous.

Gasoline and a Match.—A young man in Peru, Ind., lighted a match to find a leak in a gasoline tank shortly after dark. The result was that an hour later he was in the hospital with his entire body covered with burns. His chances for recovery are said to be poor. It appears that the gasoline tank sprang a leak and after some examination to locate this leak, a quantity of gasoline was poured into the tank to ascertain if it had been properly mended. The fumes of the gas came in contact with the flame of a lighted match and the explosion started a fire in the garage, which called out the fire department. The young man was seared from head to foot and his recovery is doubtful.

Just a Frightened Mule.—This is probably the only thing to which a serious accident is attributed in Bedford, Ind. A party in an automobile passed a man in a wagon drawn by a mule, and although the driver of the car succeeded in passing, the mule suddenly plunged ahead and seemed to be about to run into the car. The machine was overturned beside the road and the passengers were thrown out. One of the passengers had a broken neck and the others were seriously injured.

Will Need False Teeth.—Near Moundsville, W. Va., a young woman was thrown from an automobile, over the side of a bridge into a creek thirty feet below. The driver of the car was racing with another machine and not knowing the road did not slow down in time to make a sharp turn. He struck the side of the bridge and the young lady was thrown from the seat over the wall into the stream below. It was considered a miracle that she was not killed. As it was she had a good many teeth knocked out and was badly bruised.

A Drunken Driver.—A former teacher of Logansport, Ind., was run down and killed by a drunken saloonkeeper. The young man was not at all to blame and the accident is merely another illustration of the fact that whiskey is a dangerous thing to mix with automobile driving.

Tracks Obscured by Box Cars.—Two girls were instantly killed and one woman is dying as the result of a crossing accident in Jewel, Ind. The view of the tracks was hidden by a row of box cars and the front wheels of the automobile were almost on the track when the driver saw the train. He turned the car aside but the rear wheels caught in a cattle guard and the car was overturned, the rear end being thrown in front of the locomotive.

Struck an Ice Spot.—At Pittsburgh, Pa., one person was killed and three injured when a car slid across the road on an ice spot. The driver in an effort to keep the machine from being precipitated over an embankment, ran the engine faster and the car turned around twice and with the weight of the occupants on the downward side of the hill, turned turtle, killing one and injuring three as stated.

Steering Gear Broke.—One person was killed and two injured in Yonkers, N. Y., when the steering apparatus broke and the machine swerved off the macadam road into the mud and turned over, pinning the occupants beneath.

Crushed Between Automobile and Wall.—A driver of a sixteen-ton automobile, at Kenosha, Wis., failed to see a man behind his car and in backing it the man was crushed between the car and a wall and died instantly.

Slipped Down Embankment.—At Atlanta, Kan., one woman was killed and two badly hurt when the wheels of the car in which they were riding slipped and went over an embankment. The driver had turned out to allow another car to pass and drove too near the edge of the road.

Failed to Take a Curve in Time.—One woman and three children were severely injured near Orange, Texas, when the driver of the car in which they were riding did not take the curve as soon as he should, causing the car to overturn and go into the ditch. The car was completely wrecked.

Rear End Collision.—At Alliance, O., one man was severely injured and remained unconscious for nine hours, when a touring car going at a high rate of speed, overtook the runabout that he was driving and crashed into his car from the rear. He was thrown from the car and landed on his head. The touring car proceeded to strike a telegraph pole, climb a terrace and plunge into a front window of a residence, demolishing the glass. The driver of the touring car stuck to the wheel and escaped injuries.

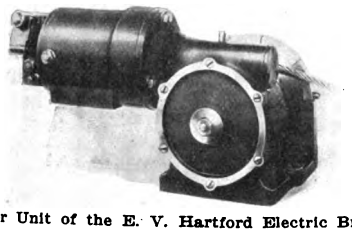
Steering Gear Broke.—Near Leipsic, Ohio, a man was driving in an automobile when the steering gear broke and the car ran into a ditch. The occupant was quickly killed and the accident occurred but a short distance from where he was born 59 years earlier.

The Life Saving Tire.—A young woman of Caldwell, N. J., was driving past a mill pond when her attention was attracted by the cries of a young man who had broken through the ice while skating. The young woman in the automobile tied a piece of rope to a spare tire which she carried and threw the tire to the man. He got it under his shoulders but the young woman was not strong enough to pull him out. She then saved the man by fastening the end of the rope to the automobile and jumping into the machine, switched on the power and had the man safely on the shore rather quicker than he relished.

A Frozen Radiator Explodes.—A young man in Ottawa, Ill., is suffering from a badly cut and scalded face, which he sustained when the radiator on his car exploded. It was noticed that steam was escaping from the radiator and that the engine seemed to be over-heating. On getting out to investigate, the radiator exploded. A piece of metal struck the driver in the head inflicting a severe cut and his face was badly scalded by steam and hot water. It is supposed that the accident was due to the freezing of water in the bottom of the radiator which stopped the circulation.

An Old, Old Story.—Near Porterville, Cal., a man was crushed to death when an automobile which he was driving turned turtle. Three other occupants of the car were injured. The car is reported to have been traveling at a slow rate of speed when the accident happened. A jammed steering gear is be-

Digitized by Google



lieved to be the cause of it. The car was going down a gentle grade, when suddenly it lurched near a high embankment. It finally struck the embankment and was thrown one side and overturned. All the passengers but the one who was killed jumped from the car. He remained at the wheel and was crushed beneath the car when it overturned.

AN ELECTRICAL BRAKE.

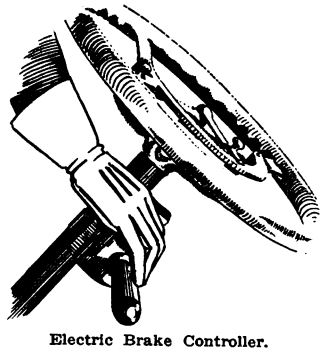
Said to Give Complete Control of the Car and to Be Entirely Satisfactory.

Every motorist knows how inefficient his brakes become when once the lining is worn through. It becomes almost impossible to slow down without locking the wheels. This sudden locking of the wheels could be overcome by the presence of oil between the brake drum and band, and allow gradual slowing down, but the presence of the oil would make it almost impossible to bring the vehicle to a dead stop owing to the fact that sufficient pressure could not be applied by either foot or hand levers.

Thousands of dollars have been spent in designing automobile axle housings and parts to prevent the grease and oil necessary for the life of the axle

Motor Unit of the E. V. Hartford Electric Brake.

from coming into contact with the brake drums and shoes.

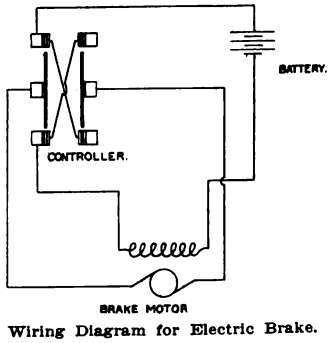


The Hartford electric brake completely reverses this order of things; the brakes are oiled with the result that a film of oil between the parts coming in contact must necessarily be squeezed out by the pressure of the brake so that the car is gradually slowed down automatically, and as the pressure overcomes the resistance of the oil, the brake becomes proportionately more effective. This eliminates any possibility of the harsh braking effect noticeable in the use of the ordinary type of brake mechanism which is so destructive to the tires. It is possible with the Hartford electric brake to drive an automobile at a speed of 50 miles per hour up to within about 35 feet of a right angle turn and easily make the turn at fifteen miles an hour.

Another result of this gradual but quick and effective operation of the Hartford brake can be seen in its relation to skidding on wet pavements. The car is slowed down gradually before the wheels are locked, so that the momentum is reduced to such a degree that there is practically none left when the wheels are stopped, whereas, with the brakes now in use the wheels are suddenly locked and the momentum of the car produces the skid.

The Hartford electric brake solves the brake problem not only on the automobile, but on every moving vehicle that uses electricity as motive power or has a generator or storage system.

The complete system is compact and light, weighing only about thirty-five pounds, consisting of a small type of the Hartford electric reversible motor, with a worm and worm wheel attached to a drum; to this drum is attached a steel cable, the other end of which is fastened to the brake equalizer arm.



The most important and novel part of the Hartford brake is the patented controller which is entirely new, so far as the control of electric motive

Electric Brake Controller.

power is concerned. It is small and compact and placed within easy reach of the driver's hand as shown in the illustration. By this new device any desired nicety and fineness in braking effect is obtainable by purely electrical means. By actual demonstration a car of 60 horsepower weighing over 4,000 pounds can be controlled by the mere pressure of one finger on the operating lever. The operation of the brake is in fact so extremely simple that five minutes' practice will make any one proficient in its use.

With this type of switch a two-point control is given. The first point supplies enough braking power for service purposes and the second for an emergency stop. Pushing the switch back to its original position immediately disengages the brake. The whole system is very simple and can be summed up in a few words by saying that the usual manual labor connected with brake operation is displaced by the wonderful energy of the Hartford reversible motor. This motor is high-speed, series wound. The current can be applied by either a six, twelve or twenty-four volt storage battery, for automobile

Wiring Diagram for Electric Brake.

or kindred usages, but heavier voltage can be used with equal success, the motor being wound for these voltages.

This motor has on the end of its armature shaft a worm which, through a reduction of 100 to 1 drives a gear. This gear in turn operates a drum by an internal gear through a reduction of 4 to 1. This gives a total reduction of 400 to 1. On the

Digitized by Google

drum is wound a steel brake-pulling cable which directly transmits the pull of the motor to the braking mechanism.

When running idle the motor is capable of 10,000 revolutions per minute, and when under load it can apply 1,000 pounds pull at about the same speed as would be the case with a quick application of the hand emergency brake. After 1,000 pounds pull is exerted on the cable a slipping clutch prevents any further pull and a ratchet prevents the brake from slipping off. Because of the powerful pull on the brake cable the brakes run in oil. The ampere draw in putting a 1,000 pound pull on the cable is 40 for 2/5 second, and the weight of this equipment for an automobile is about 35 pounds. The net weight would be less than this because the emergency brake lever and much of the linkage would be removed. The Hartford electric brake replaces the emergency set and is used constantly in service, this leaves the foot brake as originally installed for operation if wanted.

The death roll in motor-car accidents is increasing at a terrible rate, and any preventive such as a brake that will act almost instantaneously without requiring the driver to remove his hands from the steering wheel, that will be certain in its operation and that will be inexpensive to apply, and above all that will more positively insure the safety of the occupants of a motor car, is a positive advance in the art and undoubtedly has a wide field.

One great feature of this brake is that it can very easily be attached to any car now in use provided it is equipped with storage batteries.

Several Practical Suggestions.

From F. B. I., North Dakota.—If No. 1524, B. H. Prior, can get a Marvel carburetor to fit his car, I think he will have no more trouble from that source. If C. H. L., No. 1544, will also put a Marvel carburetor and an Atwater-Kent ignition system in, I think he will have a nice running car, and it will also start easy. I do not believe it pays to retread tires, the way they make them nowadays. We find it does not pay to even repair breaks unless the tire is practically new. The "dope" for repairing his radiator can be bought at most any supply store.

As to No. 1525, Gus Schleyer, he will need about a 15 candlepower bulb in each headlight to get a good light. A tungsten bulb takes about a watt and a quarter to a candlepower. A 10 watt lamp should give 8 candlepower. My theory is that the mixture in your car is too thin in starting. When the car is cold, jack up one hind wheel, open the carburetor adjustment about a quarter turn, and if you have priming plugs, prime the cylinders with a mixture of half gasoline and half ether. When warmed up adjust the carburetor.

The best book I have found on autos, and I have a good many, is "Care and Repair of Automobiles," by Clough, published by the Horseless Age, New York. This book will only set No. 1531, F. L. A., back a dollar and he will be well satisfied.

I do not believe No. 1547, E. C. W., can run his horn on a Bosch magneto for there are very few horns that will run on an alternating current.

Re No. 1548, Brizee: If you have not replaced the original timer and roller that came on your car, that is probably where your trouble lies, or possibly the vibrators are sticking.

A master vibrator will improve the running of a Ford that seemingly runs perfect, but rather than buy a master vibrator and put it on, I would get an Atwater-Kent system, then you get away from all vibrator trouble. I have put this system on several real old cars—a 1909 model 10 Buick, one of the first model "N" Fords and several others. The owner of the Buick said his car never ran better and the others "crack right along" as even as a clock. You can tell a car with this ignition as far as you can hear it by its even, sharp explosions. I am not putting them on with a "money back" guarantee. I do not want to give free advertising, but I am so enthusiastic about it, I cannot help but recommend it. Perfect ignition will cure a lot of motor ills.

If I could afford a six as No. 1542 can, I would spend $10 more and put on a Stewart vacuum system for gasoline feed, and get away from a lot of the trouble of a pressure tank.

Carment, No. 1532, is not the only one who has had an accident on account of the Ford steering gear. We use the "Little Steersman" which helps a great deal. It would seem as though the Ford company would remedy this trouble.

Oily Spark Plugs.

From E. M. Douglass, Missouri.—For the benefit of A. G. Bierbauer, Minnesota, No. 1528, February number, I will tell how I helped my Buick, 16, 1910. I had the very same trouble with oily spark plugs. They got so bad sometimes I would have to clean them in going 10 or 15 miles. The first thing I did was to use as long a plug as I could get and see that the point on the shell of the plug was down at the bottom when in place in the cylinder and the end must stand up past the point in porcelain, so that the oil cannot stand on the points and cause it to missfire. The next thing I did was to drill six 32-inch holes in each piston in the upper oil groove, slanting the holes down on the inside. I did this drilling on the front pair of pistons as I was not bothered in the others. This drilling seemed to help me some and in December I gave the car a complete overhauling and drilled four more holes in each piston, making ten holes in each one. I have not run the car much since overhauling it but I can run with the crankcase full of oil now where I could not do it before. I also lowered the oil in the crankcase just so the end of the cranks will barely tip the oil while standing level. This is very easy to do. Take off the bottom half of the crankcase and turn the crankshaft so two of the cranks are straight down. Lay a straightedge of any kind on the bottom of the crankcase and measure down to the lowest point of the crank, then put your straightedge on the top of the bottom half of the crankcase and measure down to where the oil overflows in the case, and if it is not the same as it was on the crankshaft measure cut the grooves down until it measures the same and your oil will not stand so high and the cranks dip so deep. Also be careful that the cotter pins in the ends of the crank boxings bolts are bent close around the nuts and not left full length straight out or they will help to throw more oil. I also put on two new rings on each piston a year before drilling these holes, but I could not see that they helped the oil business any until they wore down to fit the cylinder. Pistons or cylinders are not scored at all and I have good compression in all cylinders. I

Digitized by Google

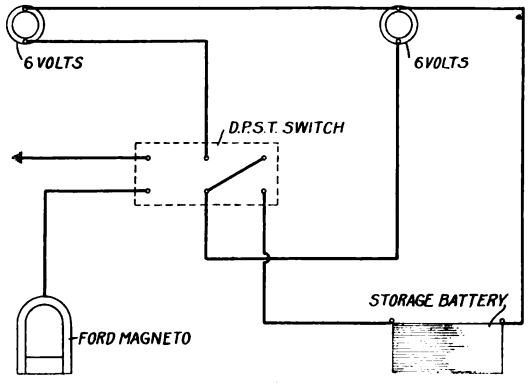
have very little trouble with my car, except I would get too much oil.

I also had a knock in the engine last summer that was hard to locate. Would notice it only when pulling real hard or running slow. I examined the cranks and took up all slack to perfect fit. The wrist pins were not loose enough to cause a knock, but I found it at last. It was a crack about six inches long just back of the magneto, on top of the hanger arm. When pulling hard the explosion in the cylinders would open this crack just a little and when it went back it would cause the knock. I had it welded and I do not hear any knock at all now. If any of the boys have a knock you cannot find, look for a crack in the crankcase somewhere and have it welded and see if the knock does not disappear. I hope this may help someone as it has helped me.

Wants Metz Car Information.

From A. W. Graham, New Jersey.—I have recently acquired a Metz 1911, 2 cylinder opposed, air-cooled machine, but on account of illness have only just started to overhaul it. I should be very much obliged to you if you could insert in your paper a short notice asking for experience with this particular model. I especially desire to know the kind of oil used and drops per minute (it has 4 sight feeds, two to cylinders and two to crankcase over connecting rods, the oil being forced by small centrifugal pump). Also the carburetor suited to this type of engine. (I had Model E Schebler, ¾ inch when I got it, but I think model 4 would be better.) Also whether the brakes are sufficient to stop it and hold it in the middle of a steep grade, and if not, if they have been able to countershaft or other brake which will do so. Also any information as to enclosing chains, lengthening frame or carrying passengers on rear seat. I have written the Metz Company for instruction book of this model, but they seem to be all out of them (although they sold them for three years) and they are apparently unwilling to give very full information of this machine. Its size, power, etc., suits me and the building I have to keep it in far better than the later and larger models. If you can give me any information by mail in regard to oiling, carburetor, brakes or running slow with magneto (which is Bosch model D. U. 2 fixed spark) should consider it a favor.

Those Missing Two Cylinders.



From Forrest Wilson, Arkansas.—In regard to No. 1534 in which Will & Co. state that they have an engine missing on two cylinders and are unable to locate the trouble, I wish to say that I am satisfied that they will find the trouble is bad connections between the intake manifold and cylinder ports on the missing cylinders. These cylinders are drawing fresh air through these points and are therefore getting very little or no gasoline. I find this to be the trouble a great many times when a motor will not run slowly or fire properly except when running at high speed or pulling hard.

Slopping Gasoline.

From A. Larson, New York.—I am just now reading the February number and will give one explanation to query No. 1542, "Snapping and Rattling." Some tanks are equipped with baffle plates to prevent gasoline from slopping. It is probably this that has come loose and naturally will cause a lot of rattle, as it slops back and forth in the tank; more so if the tank is nearly empty. I had that trouble once myself in a car with gravity feed, but after I located the trouble I took a pair of long pliers and got hold of the plate and twisting the same around, rolled it up so I could pull it out through the filler cap. I am of the opinion that this is Mr. Farrar's trouble.

Wiring for Electric Lights.

From G. H. Bolus, Ohio.—I have been impressed by the number of up-to-date cars which have had trouble in their starting system. It is usually the same trouble in all cases and is so easy to remedy. I refer to the acid from the storage battery slopping over and eventually forming a conducting path for the current, thus grounding and sometimes "shorting" the battery. An insulated battery box would entirely eliminate this trouble. It has been

Wiring Diagram.

a year now since I got a larger car (Buick 30) and sold my Ford. I never knew what real comfort in an automobile was until I got my Buick. I have worked out a system for a Ford whereby the electric lights could be used either on the 12 volt magneto or a 6 volt storage battery at will. The wiring scheme is as shown and may interest some of your readers. It is simply a series—parallel proposition.

Tire Reliners and Radiator Cement.

From Edward D. Mix, New York.—I will make a few suggestions for the benefit of No. 1544 in the February issue. Question No. 2—Had three different shoes retread, different makes. They all blew out long before I had gotten my money's worth. Retreads cost about as much (a little more) as a new shoe. No more for me! I now have "Innershoe" reliners that I will use until the shoe falls apart. I can use it then in another. No. 4—After using different makes, at the same price, I find "Se-ment-ol" the best radiator cement. It won't last forever though, maybe a month or so. I hope the above will be worth consideration.

Too much poor mineral lubricating oil will interfere with current delivery to the battery. A generator should not be tested with a six-volt battery current. It may burn out. The ordinary "monkey-wrench" mechanic should not attempt to repair a magneto or generator.

Digitized by Google

A Spark Plug Fact.

From N. G. Near, New York.—Simply because a spark plug sparks nicely outside of the engine in the open atmosphere is not absolute proof that the plug will spark well when in service. This is a point that the great majority of automobile folks do not know and have never thought about. On giving the matter a little thought, however, you can clearly understand why there should be and is a difference in spark. Sometimes a plug will not spark at all in the cylinder, whereas it sparks nicely on the outside. Outside, the atmosphere is cool, clean and under atmospheric pressure only—14.7 pounds per square inch. Inside, the spark is timed to occur just when compression is about at its maximum. The gas in the cylinder is not pure atmosphere but is a combination of burned mixture, pure air and gasoline vapor. Besides, the compressed gas is hot although not yet burning. It is quite evident, therefore, that conditions are vastly different. In a vacuum a spark jumps very readily. In the open air greater voltage is required to force the spark across the same gap. Under pressure, and at the same temperature, the voltage necessary must be still greater. However, in the cylinder, the hotness of the gas partly overcomes the pressure drawback, for a hot gas is a better transmitter than a cold one. It is well known, for instance, that a favorite place for lightning to strike is down a hot chimney. This may be due partially to the rarity of the gas, which in turn is due to the high temperature.

A Word for Repair Men.

From A. W. Manering, Illinois.—I have been driving a model T Ford car for two years and have had very little trouble, and we have some very bad roads in Southern Illinois. I was very much amused at letter No. 1521 in the January issue. The writer certainly needs to do some hard study on gasoline engines. Would suggest that he get a copy of Dyke's Automobile Encyclopedia advertised in your journal. I agree with Mr. J. M. Barber. If doctors received pay for results only they would have to change occupations. Most owners, especially of the wealthy class, don't realize how hard the work and how greasy and dirty the repair work really is. They also expect their work to be done "right now," never thinking the trouble has to first be located which sometimes is a task where there is a wire broken inside the insulation or some slight knock develops in the motor. I hope to see the time when repairmen are paid for what the work is really worth.

That Master Vibrator Rattle.

From George W. Tappan, Connecticut.—In your issue under the inquiry No. 1505, concerning master vibrator noise like two coal scuttles rattling, I think if the inquirer will put a new middle shell in his muffler he will eliminate the rattle.

Care of the Battery.

F. E. Watts, chief engineer of the Hupp Motor Car Company, is authority for the statement that 90 per cent. of battery and ignition trouble experienced by motorists during the winter is due to carelessness and negligence on the part of owners. This is due to the fact that battery education has been sadly neglected by motorists. Most people look upon the storage battery as a "mystery box," and believe the less attention it is given the better. This is absolutely the wrong attitude. If there is one thing that requires a man's attention in the winter, it is the storage battery. The battery is the very life of a car. It is the source from which the engine derives its life. If the carburetor, as has been said so often, is the lungs of a motor, then the battery is the heart. Consequently, it should be given constant care and attention by the owner.

Tire Pointers.

In order that rubber cement shall penetrate and hold well on the fabric of a casing it must be thin and perfectly free from oil. Several successive coats, allowing each one to get thoroughly dry before applying the next, will give best results in repairing cuts and tears that extend down through the tread to the fabric.

A very serviceable blow-out patch that will take you safely home may be made out of tire tape. Clean the fabric around the blowout with gasoline, and apply strips of tape, first lengthways and then crossways, until the hole is well covered. Then cover the tape with a thickness of cloth to keep the inner tube from sticking, and the patch is complete.

When rubber cement has stood exposed to the air for even a short time it becomes too thick to give best results. But great care should be used in thinning it as the common gasoline contains some oil and is not suitable. High test gasoline or bisulphide of carbon should be used as a thinner.

The tube should be rolled flat with soft cloth between the layers, a strip of cotton flannel rolled up with the tube is good. The roll should then be placed in a thick cloth bag with the stem protruding, and the mouth of the bag be tied around the stem. It is a good plan to put talcum powder in the bag.

It is generally supposed that the greater portion of the weight of a car is carried on the rear wheels. This is only true when there is a full load in the back seat. Usually the front wheels carry one-eighth more weight than the rear.

A canvas bag filled with sand having a suitable diameter makes a good substitute for an air bag in repairing casings.

For the Gasoline Leak.

From Fred Pedersen, M. E., New York.—Seeing the inquiry of A. M., Indiana, in the December issue, I would like to offer a suggestion. I have remedied the same trouble by drawing the crankshaft timing gear up against the crankcase with the starting crank jaw and putting a thin washer between the jaw and the timing gear. If the Woodruff key which holds the gear on the shaft interferes, remove the gear and shorten either with a hacksaw or file. Care should be taken in drawing the gear against the crankcase, as it is very easy to get too thick a washer between the starter jaw and the gear, which might result in some rather expensive repairs. You will lock the crankshaft to the crankcase if too thick. I hope A. M. will understand and benefit by my suggestion.

Owing to the fact that the float in the carburetor is violently agitated when the car is traveling over rough roads, the gasoline level is practically raised, and more gasoline is fed to the engine than is needed.

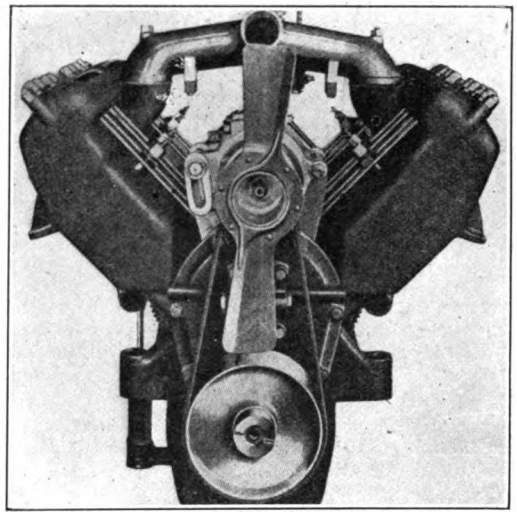
NEW 8 CYLINDER DESIGN.

The Ferro Is the Latest Type of V Shaped Internal Combustion Motor.

Among eight cylinder motors which recent development have brought to light there is one which stands out as of exceeding interest, because it is not of foreign type or in any sense a copy or adaptation. It is of truly American design, being originated by the Brush Engineering Association, of Detroit, and built by The Ferro Machine & Foundry Company, of Cleveland. The ordinary Eight "V" adopts the "L" head type of cylinder, two of these "L" head blocks at 90 degrees to each other being attached to a common crank case. The Ferro Eight "V" is an entirely different type. The motor is designed with overhead valves with detachable heads. This plan permits an Eight "V" which is even more accessible in a car than the ordinary vertical motor, either four or six. The exhaust manifold places itself low down and out of the way on the outside of the "V". The valve tappet adjustment is in the top of the cylinder head. A single riser combines the intake manifold and the water outlet manifold. This places the carburetor in a very advantageous position between the tops of the two cylinder blocks. This manifolding simplifies the carburetion problem. From the carburetor to the valve there is a continuous downward flow. This absolutely eliminates any possibility of gasoline pocketing or "loading" in the manifold. As the water outlet manifold surrounds the intake manifold, the necessary pre-heating for the proper handling of the low grade fuel to-day available, occurs at the earliest possible moment; that is, as soon as the cooling water becomes heated this heat is taken immediately to the place where it is most necessary. Such a manifolding arrangement means obviously good carburetion and a prompt and powerful response to all changes in throttle opening. The entire "V" is now left clean for the installation of the ignition outfit, and of the starting and lighting equipment.

The heads of the motor, which contain valves and valve seats with no cages, are easily detached. No expert knowledge and no special tools are required to remove these heads, clean out all carbon, grind in valves and replace them. This is a simple operation, but it absolutely assures perfectly seated valves and perfectly clean combustion chambers. The grinding in of the valves may be done on a bench, or wherever it may be most advantageous, in order that a workman may inspect his valve seats while the grinding operation is being carried on, and he absolutely sure that he has done a perfectly satisfactory job.



This design also permits, when the head is detached, the withdrawal of any piston or connecting rod assembly through the top of the cylinder bore. The use of overhead valves in detachable heads with the intake and exhaust passages cored in the head simplifies the cylinder casting. This simplification permits both cylinder blocks and the upper half of the crank case being cast in one piece.

Engineers and technical men have known that the only practical way to secure real motor rigidity was by "bloc" casting. Users have discovered that while their motor was quiet when new, its use brought to the surface a good many noises due to the improper relation of working parts.

There are no studs or bolts or nuts fastening the cylinders to the crank case, which may gradually work loose. The crank shaft and cam shaft with their bearings are both tied definitely to the cylinder block.

There are certain types of motor in which the adjustment of valve tappets really requires a "rubber monkey wrench." In the "Ferro" eight cylinder "V" there are no special tools required. The adjustment is quickly made, and it is hardly necessary for the owner-user to even turn his cuffs back. While this accessibility and endurance of the motor has been the subject of careful study and investigation, it has not been secured at the expense of maintenance cost.

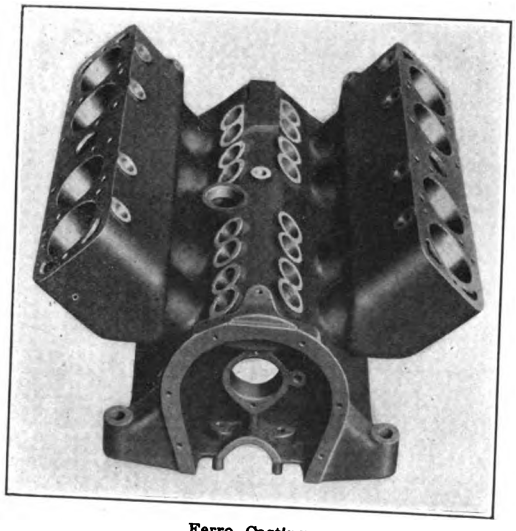
Naturally, due to their location, the valves are farthest away from the surplus oil which may work up around the piston. They are in a position where

The Ferro 8-Cylinder Engine.

the water jacketing of valve seats and valve stems may approach as nearly to the perfect as is humanly possible. There is a free and rapid circulation throughout the entire head. There is but one thickness of metal between the valve seat and the water which completely surrounds both valve openings. The metal which forms the stem guide is also thoroughly water jacketed. This provides that these valves operate at a lower temperature than any other type of poppet valve known. The result is a remarkable freedom from pitting, or warping, or carbon deposit.

The simplification of cylinder casting permitted by the use of the detachable head allows the manufacturer to make a "bloc" cylinder, the expense of which is very little greater than that of a cylinder pair of the old type.

The combustion chamber is cylindrical in shape, and has all surfaces fully machined. It is obvious that this definitely provides that all combustion shall be of the same capacity, which means the same compression, thus providing smooth, "sweet" motor operation.



The gasoline motor is really a heat engine. All heat units which the cooling water carries away

Digitized by Google

represents a dead loss. Only those heat units which are transmuted into movement of working parts are available for power development.

One of the first things which strikes the observer when inspecting this simple motor is the use of a pressed steel rocker arm in place of a forging for operating the valve. This construction is light, simple and permits of tappet adjustment merely by raising and lowering a stud carried in the center head cover.

The timing of the motor is remarkably simple. Instead of using eight cams on the cam shaft with, for each valve, an adapter or translation rocker with its necessary fastenings, the very obvious plan of providing a cam for each valve has been followed; that is, there are 16 cams integral with the cam shaft, each cam operating its valve in exactly the same manner as in the four cylinder vertical motor.

Ferro Casting.

It is plainly evident with this construction any repairman who is capable of timing and caring for four cylinder vertical can just as easily care for this engine, without any additional knowledge or skill. This cam arrangement presents an additional attractive feature in that any desirable four cylinder timing may be used.

The firing order provides such a distribution of loads on crank bearings that the resultant force is exerted very nearly in a vertical direction. The wear on the crank shaft bearing is, therefore, almost exactly as in a vertical motor. Taking advantage of this condition the crank shaft bearings and caps are all split on a horizontal line. If adjustment of connecting rod bearing becomes necessary, the operation is almost exactly the same as with the connecting rod bearing in a motor of the vertical type; that connecting rod which has a slight oscillating movement on the outside of the bronze bushing has merely to be adjusted in the same way as the main bearing adjustment is made.

The Ferro is a most highly developed type of internal combustion motor, both from an efficiency and maintenance standpoint. It presents to the American public for American use an eight cylinder "V" which does not require that either the user or the repairman must make a technical expert of himself.

Number Plate Color.

The State to which any car belongs may be distinguished by the colors of the number plates, which are as follows:

White on Green—Alabama, Maryland, New Hampshire, New Mexico, North Carolina.

No automobile law—Alaska, Louisiana, Texas, Wyoming.

Black on White—Georgia, Kansas, Kentucky, Missouri, Rhode Island, Vermont, Wisconsin, Arizona.

White on Red—Idaho, South Dakota.

White on Blue—Maine, Oregon, West Virginia, Indiana.

Yellow on Black—Delaware, Connecticut.

White on Black—District of Columbia, Montana, Nebraska, Pennsylvania, South Carolina.

Color not specified—Florida, Nevada, Tennessee, Utah.

Green on White—Illinois.

White on Dark Blue—Iowa, Arkansas.

Blue on White—Massachusetts, Virginia.

Red on White—Michigan.

Black on Aluminum—Minnesota, Mississippi.

White on Dark Red—New Jersey.

White on Brown—New York.

Black on Yellow—North Dakota, California, Colorado.

Maroon on White—Ohio.

No plates required—Oklahoma.

Light on Dark—Washington.

Black on Yellow—Alberta, Canada.

White on Dark Green—British Columbia.

Black on White—Manitoba, Nova Scotia.

White on Red—New Brunswick.

White on Black—Newfoundland.

Blue on Gray—Ontario, Canada.

Motor cars forbidden—Prince Edward Island.

Black on Pea Green—Quebec, Canada.

Black on Buff—Saskatchewan, Canada.

Tours Across the Continent.

From Thos. Lewark, Virginia.—In the past, automobile tours have been confined principally to the Central and Eastern States. The present year, 1915, will undoubtedly see these tours extended to the far West, because of the great exposition at San Francisco. Sufficient information is now at hand from those who have made this trans-continental trip, so that the fear and dread concerning the route are practically gone, and thousands will be seen this summer directing their tours to that wonderful, awe-inspiring section which rivals Europe in beauty and grandeur of scenery. The opportunity of the year will not be lost. With two great expositions in California as drawing cards, and the ever present lure of the West, together with "See America First," will certainly put 1915 as a record breaker in transcontinental touring.

Already the air is filled with whisperings of the trip, the information bureaus everywhere are flooded with inquiries, parties are being formed in Eastern cities, so that the greatest pleasure possible may be obtained en route. It will be the trip of a lifetime. The writer speaks from experience, having crossed the continent twice. When once you have looked upon the sublime grandeur and indescribable formations of those Cascades, Sierra Nevada and Rocky Mountains, and the wonderful

Digitized by Google

fertile valleys, you will understand then how difficult it is to find words to convey your inward joy.

To those of your readers who are a little timid about the roads, I would say, have no fear. I used the same car both trips and had no trouble. The worst stretch of road between Richmond, Va., and San Francisco, Cal., I found between Washington, D. C., and Richmond, Va.

Temporary Gasoline Supply.

On some gasoline tanks it is frequently the case that a collar is soldered to the tank for the purpose of accommodating the thread into which the outlet tap is screwed. It happened on one occasion when the writer was on the road that this collar began to come adrift, giving rise to a leakage of the gasoline; after a few miles the collar came right away, leaving in the bottom of the tank a hole about half an inch in diameter. It should be explained that the copper pipe came up through the footboards for about a foot to reach the bottom of the tank, the end of the pipe being fitted with a cone joint. A temporary expedient was necessary to permit a continuation of the journey, and a piece of rubber tube was used, about a foot long, of a size that would make an air-tight joint on the gasoline pipe. The other end of this pipe was inserted into the nozzle of the spare two-gallon can, splashing being prevented by the insertion of a piece of cloth into the orifice. The rubber tube was arranged with the can on the footboard in such a way that a syphon action was set up, and the device acted in a very satisfactory manner until a garage was reached, where it was possible again to solder the collar on to the tank.

Goodyear Tire Reduction.

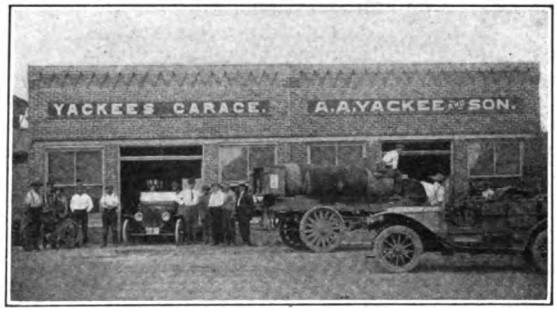
The Goodyear Tire and Rubber Company announces, effective February 1, another big reduction in Goodyear tires, the third reduction in two years, or a total reduction of 45 per cent. "Our present action," says C. W. Seiberling, vice-president, "is entirely logical, and is based on lower cost of crude rubber, the largest factory production in the world, the facilities afforded by ownership of our own fabric mill, our world-wide organization that gives us certain important advantages in purchasing crude rubber, and a desire to continue to give tire users the most for their money. In going forward on the new basis we are happy to announce several refinements in Goodyear tires, at an added cost, to insure greater service, even in the face of a price reduction." The Goodyear Tire and Rubber Company has taken over the sale of Motz cushion tires.

The Ford Oil Trouble.

From E. H. McMillan, Jr., California.—In regard to the 1911 Model T Ford troubling Mr. Myer about the oil getting up to the spark plugs too much, would advise using four leak-proof piston rings, one on each piston on the top, also would advise replacing the crankcase cover which comes on the 1911 model with later cover, part No. 3101, which has shallower oil dips.

As a rule when missing occurs in one cylinder at slow speed, and firing is right at fast speed, the fault consists of too wide a spark gap in the plug of that cylinder.

Useful Pointers.



From L. W. C., Iowa.—Once while touring we punctured the gasoline tank so that it leaked a small stream. We procured a piece of common laundry soap, mixed it a little, and plastered it over the hole and drove seventy miles without losing a drop of gasoline.

A puzzling short-circuit in the electrical wiring of an Overland Model 79 was located in the self-starter switch where the copper scrapings from the contacts had collected and caused a slow leak.

In zero weather Fords usually have to be warmed up before starting. To avoid this, I bent a piece of heavy tin around the "choker" lever on the carburetor, extending it a couple inches toward the engine. I fastened a light wire to the end of this tin lever and ran it through a copper tube up the side of the steering post, where I have a clamp, giving friction enough to resist the pull of the choker-lever spring. Now I can crank my car and drive away in the coldest weather. As soon as the engine gets warm I push the wire down a little, and if it misses when throttled down, I pull it up a little.

Enterprising and Active.

From A. A. Yackee & Son, Illinois.—We enclose herewith a postal card of our garage and blacksmith shop. We have combined these two kinds of business and find that it works very well indeed.

Looks Like Plenty of Business.

For Grease Leakage.

From W. F. Ayres, Pennsylvania.—No. 1490 in December, 1914, issue. We find A. M. of Indiana is having trouble with hard grease leakage from his gear case, which is a common thing with E. M. F. 30. Three years ago a friend of mine had this same trouble and informed me he was going to have new bushings inserted and see if any improvement could be made. After spending some time, we hit upon a plan and carried it out to his satisfaction. New bushings should be made, but short enough to admit a felt washer. The grease will press against this felt and hold it into the recess which was provided by shortening the bushing. This will do the same little trick which is done in the rear axle by inserting a felt washer to protect brake drums from escaping grease.

By wiring the feed pipe against the exhaust manifold the gasoline supply may be rendered quite warm in winter, giving greater power and using less fuel.

THE CAR OWNER'S LIABILITY.

When the Chauffeur Meets With an Accident and He Himself is Responsible for It.

It is now a well settled rule of law that in order to make the owner of an automobile liable to injured third parties for his chauffeur's negligence in operating the machine, the chauffeur must, at the time of the accident, have been engaged in the service of the owner and acting within the scope of his employment. The phrase "within the scope of his employment," or "in the course of his employment," as applied to a chauffeur in this connection does not mean "during the term of his service." All it means is "while engaged in the service of the master." Consequently, a chauffeur who is operating his master's automobile for his own use and pleasure is not acting within the scope of his employment, and the owner of the car is not liable for the servant's negligence while he is so using it. It has even been held that if the owner lends his chauffeur the use of the automobile, or gives him permission to use it for his own purposes, the owner is not liable for accidents occurring during such use caused by the negligence of the chauffeur. The chauffeur, in other words, is put in the position of any other borrower, and is alone responsible for his negligent acts. The Legislature of the State of Michigan attempted to put all question as to the owner's liability at an end by enacting a statute making the owner of an automobile absolutely liable for its negligent operation by anyone (unless the machine had been stolen), but this statute has since been declared unconstitutional by the Supreme Court of that State.—Daugherty vs. Thomas (Mich.), 140 N. W. 615.

It is, of course, usually a question of fact whether, at the moment of the accident, the chauffeur was or was not acting within the scope of his employment, and the application of the rule has given rise to a seemingly every increasing crop of litigation. It may be of interest to review the more recent decisions in which the point was involved.

The owner of an automobile in the city of New York, after having been out with the car, was, on his return, asked by his chauffeur if he would loan him the machine to go uptown on some business for himself. He said he would. The chauffeur then drove to a restaurant where he was joined by two women and a man friend. He took them uptown and was coming down Eighth Avenue when he struck a pedestrian, who sued the owner of the car. The owner was held not liable. "Beyond the scope of his employment," the court said, "the servant is as much a stranger to his master as any third person. And if the servant step aside from his master's business, for however short a time, to do an act not connected with such business, the relation of master and servant is for the time suspended and an act of the servant during such interval is not to be attributed to the master."—Cunningham vs. Castle, 127 N. Y. App. Div. 580.

This case was followed in the recent case of Davies vs. Angle-American Auto Tire Co., 145 N. Y. Supp. 341, where it was said that the question of the ignorance or consent of the master has no bearing on his liability. The jury having found that the automobile was being used by the chauffeur and his companions for pleasure purposes, it was immaterial whether or not the chauffeur had his master's consent.

The mere ownership of the machine counts for little, it is held by the Pennsylvania courts, without a development of the whole circumstances. In an action for injuries received by being run down by an automobile in which was a party of four, the evidence established that the driver was in the defendant's regular enmployment as chauffeur, that the machine was intrusted to his care and keeping, however, only for the defendant's use as he might direct. But the evidence also left it clear of all doubt that the three persons occupying the machine with the driver were there by invitation of the latter, and were entire strangers to the owner of the machine, and also that the machine was being employed by the driver on this occasion without the knowledge of the owner. While the driver had it in mind to stop in the course of the drive at a store where automobile supplies were sold, to purchase some spark plugs for future use in connection with the machine, it was clear that this purpose was simply incidental to the evening's trip, and was suggested by consideration of the driver's own convenience. The owner of the car was held not liable.—Lotz vs. Hanlon, 217 Pa. St. 339.

In another case it appeared that at five o'clock on the day of the accident the defendant's chauffeur took his automobile from the place where it was kept, drove to the defendant's store, and awaited orders. He was told to get his supper and be at a certain hotel with the automobile at a quarter before seven o'clock. After he had eaten his supper, however, instead of taking the car to the hotel, he drove a mile or two distant from his boarding place, and in an opposite direction from the hotel, for the purpose of calling on a friend. At the time of the accident he had finished his call and was on his way to the hotel. It was held that he was acting beyond the scope of his employment and his master was not liable.—Danforth vs. Fisher, 75 N. H. 111.

The following case displays still another claim of circumstances. The defendant owned an automobile, which broke down on the way from Atlantic City to Philadelphia. He left it in charge of his driver, with directions to repair it and bring it on to Philadelphia. After the driver had reached the Delaware River and while waiting for the ferry, he consented to take a third person in the machine to a place about a mile back on the road, and while making such trip, through his negligence in running too fast, he came into collision with a horse and buggy on the highway, by which the plaintiffs were injured. It was held that under such circumstances the defendant was not liable for the injury. —Patterson vs. Kates, 152 Fed. 481.

A servant of the defendant had been ordered to take a car from one garage of the defendant to its other garage, there to wash the car and put it up for the night. After he had driven the car to the garage as directed, without permission or authority from the defendant and against his express general orders, he took the car to carry another employee to his home. After driving to a restaurant for his supper he was returning to the garage when the accident happened. For the reason already stated, the defendant was held not liable for the chauffeur's negligence.—Colewell vs. Aetna Bottle & Stopper Co., 33 R. I. 531.

A case very frequently cited by the courts is that

Digitized by Google

of Steffen vs. McManglaton, 142 Wis. 49. The chauffeur's contract with the defendant, the owner of the automobile, was to perform the usual duties of chauffeur during the day. The defendant did not undertake to furnish him his meals, and for his mid-day meal he was allowed to go to his home, about one mile distant from the defendant's residence, where the automobile was kept. He usually walked to his home for this meal. He had used the automobile for the purpose probably ten times without obtaining the permission or consent of the defendant to do so. He used the automobile on the day of the accident, and was going to his home for his dinner when it occurred. It was contended by the plaintiff that the chauffeur was using the automobile to further his defendant's interests: that he thereby reduced the time for getting his meals and thus was able to devote more time to the service of the defendant. It was, however, held that he was not acting within the scope of his employment, and the defendant was held not liable for his negligence.

The following are some cases where the owner was held liable. The owner of an automobile, while on a business trip in his machine, made his headquarters at an hotel; his automobile was kept in a garage several blocks away. On the evening of the accident for which he was sued, on arriving at the hotel, he told his chauffeur he was going out that night and directed him to go downstairs in the hotel and get oil. Instead of doing so the chauffeur drove the automobile to the garage for the oil and while on his way there the collision occurred. It was held that the question whether the chauffeur was acting within the scope of his employment was properly submitted to the jury, although in this particular instance the use of the machine was in disobedience of the master's literal instructions. The jury found for the plaintiff.—Bennett vs. Busch (N. J.), 67 Atl. 188.

The owner of an automobile had been driving the machine, and when he reached his place of business, stepped out. His employee thereupon, with his permission, attempted to turn the machine around, when a collision with the plaintiff's buggy and team occurred. It was held that the driver was not acting independently, but was serving his employer, and was within the scope of his employment.—Thomas vs. Armitage, 111 Minn. 238.

A chauffeur who had taken his master to a theatre, was told to be back there at a certain time, and loaned money from the master for a hair cut. After going the round of the barber shops to find a barber at leisure to attend to him, he was returning to the theatre when he ran into a person, who sued the master. It was held that the chauffeur in this case was acting within the scope of his employment, and his master was liable.—McKiernan vs. Lehmaier (Conn.), 81 Atl. 969.

It has been held, more than once, that the driver of an automobile who surrenders the actual driving of the car to another is acting within the scope of his employment, and the owner of the car will be held liable if an accident occur. This is particularly likely to happen in cases of demonstrating automobiles to prospective purchasers. Where the chauffeur of a car which was being thus demonstrated together with the sales agent and an employee of the prospective purchaser were driving in the car, the sales agent suggested that it might be well to let the employee run the car. The chauffeur acquiesced, because he thought this would be a good way to demonstrate the quality of the automobile. The employee, being inexperienced, negligently ran the car onto the sidewalk, injuring a pedestrian, who sued the seller of the car and the prospective purchaser. The seller alone was held liable, because the chauffeur's act in surrendering the driving was within the scope of his employment, while the purchaser's employee's acceptance of the proposition to ride in the car and his subsequent acceptance of the invitation to run it were outside the scope of his employment.—Wooding vs. Thom, 148 N. Y. App. Div. 21.

Again, where a demonstrator surrendered the wheel to a prospective purchaser who had had only an hour's experience the day before, and the latter ran down and injured a person in a crowded part of the city, the pedestrian sued the seller and the purchaser. Negligence was admitted and the only question was which was liable, or were both. It was held that the seller alone was liable, his chauffeur having complete control of the driving of the car, which he had no right to surrender to the purchaser under the circumstances. In another case it appeared that immediately before the accident the defendant, who was the owner of the automobile, had gone accompanied by his son and coachman, to the railway in his automobile and had left it there; that at the time of the accident his son and coachman were the occupants of the car and that the son was guiding and controlling it. It was a disputed question whether the defendant on leaving the machine had committed its custody to his son or to his coachman. It was held that the court might properly charge the jury as follows: "If the jury find either that the defendant left the automobile in charge of his son to take it home, or in charge of his son and coachmen together to take it home, or in charge of the coachman alone and the coachman neglected his duty in that regard and allowed the son to run the machine, and by the negligence of the son the accident occurred, without contributory negligence on the plaintiff's part, then in either case the defendant is responsible and liable for that negligence and its consequences." The jury found for the defendant, and, an order to set aside the verdict being granted and affirmed on appeal, the parties were left in the position in which they were before the trial.—Colard vs. Beach, 81 N. Y. App. Div. 582.

It will be seen from consideration of these cases that while the rule is clear, its application may sometimes be attended with difficulty, especially when, as frequently happens, the evidence is conflicting as to the facts.

REPAIR PARTS.

How to Know What is Used and to Find What is on Hand.

From W. Robinson, Georgia.—I have noticed in several automobile magazines that there is often some discussion of the problem of the dealer, and I have thought that the keeping of a stock of repair parts must not be among the least of them. For some time I have had charge of a stock room, and since I have been there we have installed what seems to me to be a particularly fine card system. By means of this card system we are able to tell at a glance exactly how much, or how many, of any particular part we have on hand, and are also in a position to take stock at the close of any day's business.

Digitized by Google

Thinking that it may help some one else, I am going to pass it along.

We had a quantity of cards printed, about 3½ by 5 inches, ruled and headed like the enclosed illustration. This specimen I have made up just as if it were a card in my stock room, and a careful study of it will show that practically all the information that could be wanted is on the card. In the first column, the catalogue number of the part is 2517. The name is differential case bushing. The maximum number to carry in stock (for our size room) is 8; the minimum is 4; the code word is "accite," in case we need to wire for any, and the price is 30 cents. The "Location Number" applies to the whole card, and it will be explained later. A possible improvement on the card would be to state the number of each part required per car, which would be 2, 1 and 10 respectively, on the sample card.

When the system is installed, say we have 7 of the number 2517 on hand. It goes in the bin num-

4	5	6	7	9
2517	2521	252413	2528	
2518	252113	2525	2539	
2519	2522	2525 B	2530	
2512 A	2522 B	2526	2532	
2520 B	2524	2527	2547	
RED	GREEN	WHITE	RED	GREEN

NUMBER OF PARTS	2517		2518		2519	
NAME " "	DIFFERENTIAL CASE BUSHING		DIFFERENTIAL DRIVE GEAR		DRIVE GEAR SCREWS	
MAXIMUM	8		18		50	
MINIMUM	4		9		25	
CODE WORDS	ACCITE		ACCOST		ACCOV	
PRICE	$.30		$4.00		$.02	
LOCATION NUMBER 4			13		46	
FIRST DAY	7		10		35	
SECOND " SOLD 2	5		8			
ORDERED 5 MORE						
THIRD DAY SOLD 2	3					
FOURTH " " 1	2					
FIFTH DAY NONE SOLD 5 MORE PUT IN STOCK	7					

Stock Cards.

bered 2517, and "7" is put on the card (see specimen). Next day two of them are sold, so right under the 7 we put the number left, 5. The next day two are sold, and the day after one, which leaves only two on hand, but when we sold the first two it left only one more than the minimum, so we ordered five more. The number ordered depends on how fast the part sells. A slow seller would only be to order enough to make the maximum. On the fifth day our order arrives, and we add the number received to the number on hand, which makes seven again. Column 2 shows No. 2518 below the minimum, and it is time to order ten more; 2519 still has ten more than the minimum. At the end of the day the sales books and invoices are posted direct to the cards. By this method, it is easy to see, all information is conveniently arranged, the cards gone over twice a week and an order made out. Stock can be taken at almost any minute, and by comparing the stock according to the cards, and the stock by count in the bins, thefts and waste can be detected at once.

The bins are divided into tiers, 6 bins high, and 1 bin wide (this can be varied to suit the stock). Each tier has a number (see enclosed diagram) and the edges of all the bins in that tier are painted a distinctive color. The numbers of articles too large to go in bins are put separate from the others, on a card, the location number of which is "Office," and the parts are then placed in a convenient place in the room. Accessories, etc., all are card indexed in the same way, and the cards are subdivided in the box into groups, each under its separate head by cards with tabs bearing the name of the division like "Rear Axle," "Front Axle," "Steering Gear," "Transmission," "Accessories," etc.

CARBURETION ANOMALIES.

The Problem of Proportion of Fuel to Air and of Vaporization.

P. S. Tice to the Indiana S. A. E.—As time goes on, a more intelligent recognition is being accorded those physical phenomena which inherently occur in the act of carburetion of air with a liquid fuel or its vapor. Each of these several phenomena is in itself an event the progress of which follows an inflexible rule, capable of simple and straightforward statement. But the conditions under which the act of carburetion must go forward bring into the matter variables in the correlation of simultaneous phenomena. And these variables are often most difficult of reconciliation with the desired result.

At the outset, in motor-propelled vehicles, the nature of our fuels places a limitation upon the sort used—it must be liquid. This immediately brings into being the two main problems of carburetion; proportioning of the mixture ingredients; and vaporization of the fuel. While the performance of the two functions of the carbureting device cannot be said to be diametrically opposed in character, it surely does not follow that excellence in the performance of one of them presupposes an equally meritorious result in the other.

It has been stated that there are essentially two problems, namely: proportioning of the fuel to the air and vaporization of the fuel. Let us first run through the points involved in the satisfaction of each, as if it stood alone; and later let us see the state of agreement or disagreement in the carbureting system following the attempt to make the two functions go on simultaneously.

In the following there will be no reference to this or that type of carburetor, as distinguished from its fellows. In each case and in each make of device the results attempted are, or should be, the same. Starting at this point, the field is cleared for an abstract consideration of the relations of principles and methods.

In all carbureting devices to date, capable of satisfactory use in motor cars, the liquid fuel is brought into the presence of the air with which it is to combine by means of a pressure depression exerted upon the discharge end of a passage so located as to cause the fuel to be carried off by a moving column of air. This is the fundamental point of similarity in carburetors. But here this basic similarity ends, since at least two variations are employed to create this depression on the fuel passage exit. In any case, it is sought to control the quantity of fuel discharged by virtue of this depression to give a relationship, or set of relationships over the range of the motor, between the quantity of air and quantity of fuel aspirated by the motor.

The possible variations in the means and combinations of means used to accomplish this result constitute the most interesting phase of carburetor

Digitized by Google

design, as we know it. All embrace the following two items, either singly or in combination: (1) variable depression on fuel orifice or orifices; and (2) variable fuel orifice or orifices. That the possibly usable variations are almost endless is proven by the great variety of devices with which the market is stocked.

But, whatever may be the means of securing proportioning, and whatever may be the degree of its perfection under constant conditions, it is subject to irregularities as a result of temperature change. By this is not meant seasonal changes of atmospheric temperature alone, since most carburetors provide means for compensating in large measure for this variation. The most mischievous temperature change is that due to the activity, or lack of activity, of the motor itself. Naturally the temperature changes from the latter source are greatest, and therefore most difficult, with low atmospheric temperatures; and, as a consequence, irregularities in mixture proportioning are greater in the cold than in the warm months.

Change in temperature, either of the air entering the carburetor, or the carburetor water jacket, or of the motor proper, works to change mixture proportions in the following ways:

(a) If the air entering the carburetor is subject to temperature change from moment to moment, or from hour to hour, as is the temperature under the hood of the car, the depression of pressure in the carburetor, with a given throttle opening, is ordinarily changed somewhat inversely as the temperature. This effect, while small, rather tends to maintain than alter proportions. But, unfortunately, it is not unaccompanied by effects of considerably greater magnitude, which operate in the other direction. Not only are the surface tension or capillary and the internal friction or viscosity of the fuel lowered with temperature increase, making for a considerably higher discharge rate under unchanged depression, but the coefficient of efflux of the nozzle or jet increases with a rising temperature. The converse is, of course, equally true. The result is that mixture proportions cannot be maintained in the face of changing air temperature, without readjustment of the carburetor.

The remedy in this case lies in providing means for running normally with the air entering the carburetor at a temperature considerably higher than the highest atmospheric temperature likely to be encountered throughout the year. Such an expedient, of course, requires a control, automatic or otherwise, to minimize changes in normal air temperature. In this way the effect of air temperature change can be confined almost wholly to the period of "warming up."

(b) If the temperature of the entering air remains practically constant, the effect of a carburetor water jacket is identical with that noted for change of air temperature. Of course its effect is not nearly so great, since the jet or nozzle temperatures most nearly follow those of the air-stream passing. On the other hand, if both air and jacket temperature vary, the disturbance in this case may be much greater than in a device without jacket.

(c) In the case of the motor proper being the only temperature variable, conditions, so far as proportioning is concerned, are considerably improved, since the effects upon the carburetor, as noted, will be only those due to atmospheric temperature changes.

In the foregoing no cognizance is taken of the means incorporated in the carburetor to secure proportioning throughout the range of the motor. A discussion of these things would hardly serve at this time, since their merits or demerits, as compared with each other, are matters of personal opinion rather than facts or truths universally recognized. The fact it is attempted to point is that no matter what the type or device, there is no irregularity in proportioning occasioned by a change in its working temperature.

There are further considerations in the proportioning of the mixture ingredients, but, from the manner in which they are bound up with that other function of the system, vaporization of the fuel, it will be better to take them up later when their full significance can be more easily presented.

It is admitted without question by all who have done work in this direction that the more nearly the process of vaporization is carried to its completion before the ignition of the mixture, the more flexible and responsive will be the motor, and the more economical can be its operation. But in this direction, as in most others, there are limits beyond which it is neither advisable nor necessary to go.

It is coming to be realized that to secure complete vaporization of the fuel before its entry into the cylinders is bootless, since in the cylinders themselves, after they are at working temperatures, we have a most powerful aid to vaporization. Nevertheless, as most of us know, there is much to be done before we can sit back with the bland self-assurance that the process of carburetion is being completed for us by an accommodating motor.

Let us sum up a few of the facts in the case. To get the greatest possible volumetric efficiency in a motor is desirable. This means that mixture temperatures must be kept down. To accelerate the process of vaporization is equally desirable. But this latter in its accomplishment presupposes a heat input, which, unless it can be entirely represented by fuel vaporized before the entry of the mixture into the cylinders, represents a loss in possible volumetric efficiency. It is recognized, of course, that up to a certain point such a loss in volumetric efficiency is, in practice, more than justified by the improved vaporizing conditions. Almost every one has had experience of this.

Another way to accelerate vaporization, and one, by the way, that should in all cases be carried to the limit, is to make the most of the heat supply available in the air, without resort to outside or forced supply, by subdividing the liquid fuel as finely as possible upon its entry into the air-stream. Quite remarkable results have been accomplished experimentally in this way.

No matter what is done to the fuel in the way of spraying or atomization, a certain amount of heat must be taken up by it before it can be vapor. This quantity, called the total heat of vaporization, is, for ordinary gasoline of from 58 degrees to 60 degrees Baume, and an initial temperature of 60 degrees F., in the neighborhood of 370 B. T. U.'s per pound. That the heat of compression alone is several times greater than sufficient to accomplish the transference of the whole of this amount is obvious. But the time in which it can do so is very limited; and, more important still, the fuel is very seldom

Digitized by Google

present in the cylinder in such form as make so rapid a transfer possible.

The fact that it is not, is proven when it is considered that the transfer of 375 B. T. U.'s from 15 odd pounds of air to 1 pound of fuel represents only some 84 degrees to 85 degrees F. temperature drop in the air, assuming no other interchange. In the circumstances, other interchanges do take place, and they are very difficult to measure, or eliminate, even experimentally.

The writer has certain data on temperature drop through the carburetor, the temperatures being measured in the air-making port of the carburetor, and at a point four inches above the jet, which show a maximum drop of 139 degrees F. The carburetor used was one giving extreme atomization of the fuel, and the temperatures used were high, that at the intake to the carburetor being 248 degrees F., and that of the mixture 109 degrees F. Some of this drop is accounted for by direct radiation and convection from the carburetor metal, and by the expansion of the air through the throat-piece surrounding the nozzle; but, in any case, since this was the greatest drop in temperature that could be obtained, it is certain that the fuel was vaporized almost completely even at four inches beyond the jet. With this same carburetor it was found that no gain was made in economy of operation with a temperature drop greater than 76 degrees F.

If it is taken, as it safely may be, that 85 degrees temperature drop, without other interchange, represents complete vaporization of the fuel, then, calculating losses in the same proportion as when the maximum drop of 139 degrees F. was obtained, we have.

Total Temp. Drop.		Due to Vaporization.		Loss.	
139	—	85	=	54	in the one case.
76	—	46	=	30	in the other.

From this it appears that when gain ceased from increased vaporization in the carburetor, approximately only one-half of the fuel discharged from the jet had been vaporized. Since it is inconceivable that less than complete vaporization should be conducive to greater economy than complete vaporization, it seems that the heat of the cylinders and of compression can be relied upon to complete the latter and more difficult half of the process of vaporization.

This premise seems to be supported by another experience. In some work on kerosene fuel, preliminary to the design of a carbuertor for that fuel, it was found that the most economical mixture temperature, over the whole range of the motor, was 160 degrees F., in face of the fact that vaporization of the kerosene was known to be incomplete in the carburetor at temperatures less than 288 degrees F.

The above figures are not offered as being conclusive, but only as evidence in support of the statement that, in vaporization in the carbureting system, there are limits beyond which it is neither desirable nor necessary to go.

There is one point on which they are very conclusive, however; a very considerable part of the total heat applied in an attempt to secure vaporization remains in the mixture as a temperature value, thereby greatly reducing the volumetric efficiency of the motor. And this is equally true, no matter in what way the heat is applied.

While on the subject of vaporization, it seems to be well to enlarge a little upon the prime importa of securing a very fine mechanical division of t fuel upon its entry into the air-stream. Not o can vaporization be accelerated in this way witho any very extensive recourse to heating and its co plications, but, as accompanying advantages, t carburetor becomes less sensitive, the motor mo economical and responsive and, last but not lea loading can be eliminated.

As far as we have gone in the foregoing, thr points have been brought forward, namely: (1 That temperature variations in the carburetor di turb mixture proportions; (2) that heat supply mu be made to secure a sufficient vaporization, and (3 that the necessary heat supply for vaporization ca be greatly reduced with a proper atomization. Th statement of another point (4), that the mor nearly vaporized the fuel at the time of ignition, th leaner the mixture that can be used to secure given result or output, completes the list the write desires to present.

Let us see how these four premises agree in th operation of a carbureting device. The fact tha proportions are disturbed by changes of temperatur does not fit in particularly well with the fact tha heat must be supplied to secure a sufficient vaporization. If the second premise is acted upon, there are bound to be temperature variations in the carburetor. If heat is applied only after the mixture is clear of the carburetor, mixture proportions are not apt to be disturbed by it.

But, is it then possible so to apply the heat as to secure rapid vaporization? The writer believes that it is at least much more difficult to do so. This belief is based on experimental evidence, which shows that of all portions of the intake passage, that immediately beyond the carburetor is most effective in securing vaporization. And the reasons are not far to seek: When the fuel leaves the jet it is subdivided more or less finely, and is entrained in the air in comparatively small portions, each distinct from the other. Thus, the ratio of its surface to its volume is great, and vaporization progresses rapidly. After the mixture has entered the distributing branches, but very little of the unvaporized fuel remains entrained, because of the effect of the bend or bends. The greater portion remaining unvaporized is in contact with walls, thus reducing the ratio of exposed surface to volume of liquid.

The third point, that atomization largely relieves the need for heating, seems to offer a measure of relief. But, as stated in the preceding paragraph, the time to apply the heat is while the fuel is entrained and suspended in the air-stream. And, of course, this argument applies with the greater force the more perfect atomization, and, therefore, the entrainment.

The fourth statement, of the dependence of mixture proportion upon the degree of vaporization, clashes strongly with that on the effect of temperature change upon mixture proportions. As a result of increased carburetor temperature the mixture becomes enriched, when, in fact, it should become leaner, to fulfill the requirements of economical and satisfactory operation.

Always slow down at corners, sound your horn, and keep on your right side of the road when taking them.

NEW AND INTERESTING THINGS IN MOTORDOM

Manzel Engine Driven Tire Pumps.

These pumps are especially made for use on Ford cars and they are driven by the engine. The manufacturers state that one of these tire pumps will inflate any Ford tire in less than two minutes, and can be installed by anyone. There are no holes to drill or machine work of any kind to be done in making the attachment, and the pump sells for $7.50 complete. For those desiring a larger tire pump for cars other than the Ford, or for garage use, the same manufacturers have a two-cylinder tire pump which is sold for only $20 complete with fittings, and these fittings can be furnished for over 150 different models of cars. Write to-day in regard to this line of pumps to Manzel Brothers Company, 321 Babcock St., Buffalo, N. Y.

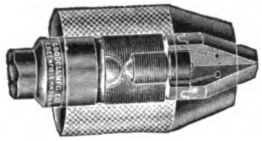
The Cataract Auto-Vehicle Washer.

This is a very simple but effective device for washing an automobile. It may be readily attached to your garden hose and it cannot scratch or streak the varnish, as a soft mop is used. With the stop cock handle and mop complete the price of the Cataract vehicle washer is $2, with plain handle and mop, $1.50, and with short handle and mop, $1. Extra mops, 50 cents. Extension handle to enable you to reach all parts of the car, 50 cents extra. Send your orders and inquiries to the Cataract Auto-Vehicle Washer Company, East Belmont Ave., Topeka, Kansas.

Change of Name and Address.

The Commercial Specialty Company, formerly located at 405 Commercial Bldg., Cleveland, Ohio, has changed its name to the Commercial Mfg. Company, and they have also moved to 508 Commercial Bldg., Cleveland, Ohio. This company manufactures the Commercial Auto Lock which is a practical attachment, that holds the starting lever of the car in neutral position, making it impossible to connect the engine with the driving mechanism. The price of this device is $2 complete prepaid to any address in the United States.

Affa Clevis Silencer.



This is a device for taking up the looseness in the brake rod preventing vibration and rattle. It is guaranteed by the manufacturers to last for the life of the car and can be attached readily to any car. This handy device retails for only 50 cents and will be sent to any address in the United States for this price. Address W. S. Graffam & Co., Northampton, Mass.

Cigars on Trial.

When a cigar manufacturer is willing to send you a box of cigars and gives you the privilege of smoking ten out of the box, to decide whether you like them or not, he must be pretty sure of the quality of such cigars. This is what Herbert D. Shivers, 913 Filbert St., Philadelphia, Pa., will do for every reader of the Automobile Dealer and Repairer who is a smoker. See his advertisement on another page. All you have to do is to write to him, tell him you saw his announcement in the Automobile Dealer and Repairer and would like to test his panatelas, telling him whether you want a mild, medium or strong cigar, and the cigars will be sent to you, postage prepaid. You smoke ten and if you don't like them, send them back at his expense, understand, not yours. Now that seems to be about as fair a proposition as any cigar manufacturer could possibly make.

The Greenfield Drill Chuck.

This is a strong, accurate, and well-made drill chuck at a popular price, ond it is especially adapted for use in automobile garages and repair shops. The shell is one piece, and the jaws are of tool steel, carefully hardened and tempered. It has ball-bearing thrust, and the thread of the shank being concealed, there is no chance for it to become bruised or injured. The bearing in the Greenfield Drill Chuck is in the center of the shell, which produces an accurate and more reliable chuck than when the bearing is at the extreme rear. The

A Good Drill Chuck.

chuck has such a strong grip that no spanner wrench is required to tighten, but one is furnished with the two larger sizes, as occasionally one is needed to loosen. The shank forms part of the chuck, making it complete, ready for use. For prices and full particulars write to the Goodell Manufacturing Company, Greenfield, Mass.

Metal Spinning and Lamp Repairing.

Automobile owners who have old broken lamps should not throw them away because in many cases these lamps may be repaired and made as good as new. Work of this kind is done, and done well, by Collins & Hatch Co., 150½ Elm St., Amesbury, Mass. The same company does metal spinning of all kinds for the trade and makes a specialty of experimental work. No order for this work will be too small to be considered, or they will be glad to figure on larger contract work for the trade. Samples, blue prints, or specifications should be sent for estimates. Prompt service and reasonable prices are guaranteed.

An Improved Machine for Reseating Valves.

No longer need garage and repair men devote four or five hours in regrinding valve seats. H. G. Paro, 719 Michigan Boulevard Building, Chicago, is marketing a device which does the work in one-fourth the time required by the old-fashioned hand method. The machine is known as the Fosnacht valve reseater. In addition to the time saved by the operator of this machine, absolutely accurate work is insured by its use. Further, no oil or emery is needed where the machine is employed, making its operation a clean process. It often saves the reboring of cylinders and the replacing of rings. By its use the maximum efficiency is obtained by the repairmen. It occupies very little space in the repair kit, and is handy to carry and to use. Every person doing valve reseating should by all means send for the booklet sent free and find out all the splendid features which recommend the appliance.

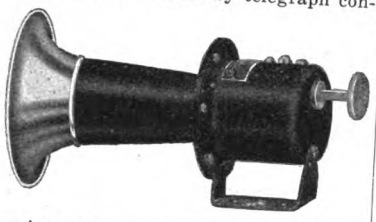
Krit Motor Car Co. Reorganized.

There has been a complete reorganization of the Krit Motor Car Company, and this will interest many dealers throughout the country, as since the temporary receiver was appointed for this company, December 28th, there have been a large number of inquiries regarding the future of the enterprise. It is now stated that the new concern is amply financed and it is believed that permanency of the Krit Motor Car Company is insured. The product of this company is too well known to need exploitation and their factory is located at Detroit, Mich.

Greenfield Taps and Dies.

The Greenfield Tap and Die Corporation of Greenfield, Mass., which is comprised of the following screw cutting tools' manufacturers: Wells Brothers Company, Wiley & Russell Mfg. Company and A. J. Smart Mfg. Company, has made the following changes in its New York, Philadelphia and Chicago stores: The corporation maintains now one store only in New York, which is located at 28 Warren St., the former location of the Wiley & Russell store. The Wells Brothers Company's store at 107 Lafayette St. has been discontinued. In Chicago, the Wiley & Russell Mfg. Company's store at 545 West Washington Blvd., has been discontinued, and the stores consolidated at 13 South Clinton St., the former location of Wells Bros. Company's store. At both of these stores as well as at 38 North Sixth St., Philadelphia, a complete stock of Wells Bros.', Wiley & Russell Mfg. Co.'s and A. J. Smart Mfg. Co.'s goods are carried. The consolidation of the stores in this manner makes a very decided improvement in the service offered by the different companies, as a much more complete and varied stock is thereby displayed for the needs of the many users of taps, dies, screw plates, reamers and other tools and machines of interest to those interested in screw cutting. Each of the stores has its same competent management as in the past and careful attention to all orders will be given as heretofore.

Imperial Welding and Cutting Equipment.



This is a complete oxy-acetylene welding and cutting equipment manufactured by an excellent firm in the best possible manner, and offered at a reasonable price to the trade. Write to-day for prices, and full particulars to the Imperial Brass Mfg. Co., 520 South Racine Ave., Chicago, Ill.

Subscribe to the "Automobile Dealer and Repairer," $1.00 Per Year.

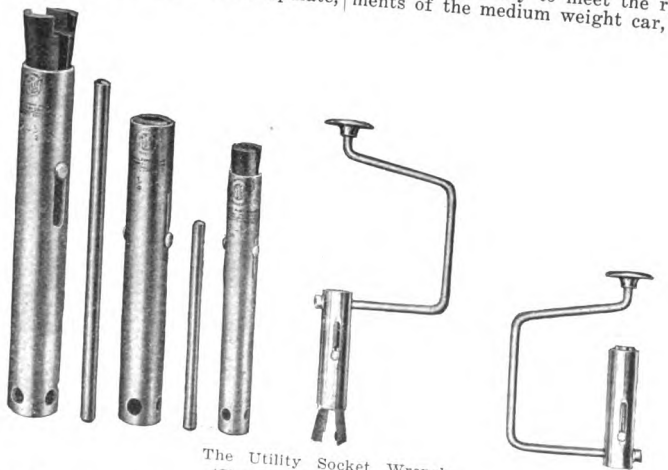
Klaxon to Bring Out $4 Hand Horn.



The Lovell-McConnell Mfg. Company, Newark, N. J., makers of the Klaxon, announce a new hand signal ready for delivery May first. It is called the Hand Klaxonet and retails at Four Dollars. The Hand Klaxonet operates on an entirely novel principle. The plunger projects from the back rather than from the top. It operates at the slightest touch and a slight movement produces a very loud note. Development work on the Hand Klaxonet has been going forward for the past few months. The Hand Klaxonet carries the regular Klaxon permanent guarantee and has standard Klaxon quality built into it. The Klaxon salesmen were notified by telegraph con-

cerning the new instrument and were given no other information than that the Klaxon makers would produce a new hand instrument, listing at four dollars and carrying regular Klaxon finishes and guarantee. On the day they received these telegrams they sent in orders for nearly ten thousand instruments. They had no idea what they were selling and the Klaxon customers did not know what they were buying. They merely knew that the company announced a four dollar instrument and when they said that the instrument carried the Klaxon guarantee it was enough for them. This is a remarkable example of the confidence in which the trade hold the Klaxon name and reputation for quality.

The Utility Socket Wrench Set.

This set illustrated herewith, has all the advantages of socket wrench sets, consisting of fourteen wrenches. Instant in adjustment. No screws to manipulate,

The Utility Socket Wrench
(Showing Method of Use.)

or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench. The illustration tells the story. This wrench set is made by the Hill Pump and Valve Co., 18-20 E. Kinzie Street, Chicago, Ill., to whom all inquiries should be addressed. This set sells for $2.50 complete.

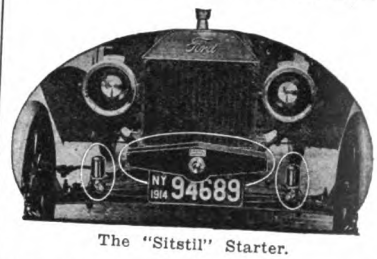
Catalogue of Ford Specialties.

Dealers, garage owners and repairmen are urged to write to Charles Friedlander & Co., 56-58 Warren Street, New York City, for their free 56-page catalogue of Ford specialties. This house sells goods at wholesale exclusively and not to consumers at any price, and in applying for the catalogue it is necessary for you to identify yourself as a dealer or repairman by means of your letter head or business card. The catalogue is an extremely interesting one, and it illustrates a line of goods which ought to interest every dealer.

The Handy Blow Torch

This is a new torch which has just been put on the market, and it is extremely handy for all car owners, dealers or garage men. It is made of heavy solid brass, including the pump, and it will hold one pint. For use in soldering, repairing terminals and lamp clamps, and other parts of the car, this is an extremely handy tool. It sells for only $3, and all inquiries concerning it should be sent to The Handy Torch Company, 69 Genesee St., Utica, N. Y.

Rubber Automobile Sundries.



These are manufactured in great variety for the trade by the Essex Rubber Co. of Trenton, N. J. Their line includes blow-out patches, reliners, tire plasters, outer boots, unvulcanized shoe liners, radiator hose, and almost everything that can be imagined in the way of rubber specialties for the automobile. Readers are urged to write for the illustrated catalogue, issued by this Company, which will be sent free for the asking.

The Right Shock Absorber.

This is a twin cylinder shock absorber designed especially to meet the requirements of the medium weight car, and is especially adapted for cars weighing from 1,800 to 3,500 pounds. This is a high class necessity for any dealer and it sells readily. The price of this Shock Absorber is $15 per set, and is guaranteed for life. Address all inquiri and orders to the Right Motor Specialti Co., 1320 Michigan Ave., Chicago, Ill.

Two Live Ford Specialties.

We illustrate two of the Ford Specia ties, which have been placed on the ma ket by the Troy Auto Specialty Co. o Troy, N. Y. One of these is the Sitsti Cranker, which starts the car from th seat every time, and with not nearly a

The "Sitstil" Starter.

much effort as in cranking. The Sitstil turns the Ford motor over five times as fast as you can crank it by hand. It is operated by a foot pedal, and it can easily be done by a lady or a child. The price of the Sitstil Cranker is $15 and it will be put out if desired on ten days' trial, and if it does not give full satisfaction the money will be refunded.

Another specialty manufactured by

the same Company is the Tasco Shock Absorbers for Ford cars. This appliance is built of steel, and it is designed for hard service. The cost is only $6 for the full set of 4, and this shock absorber is made of the finest material, properly designed, and with strong lively flexible springs. Live demonstrators are wanted.

Knowlson's Spring Leaf Spreader.

The manufacturers of this device claim that it gives 100 per cent. easier riding and stops the squeak. It is a practical, durable tool for spreading spring leaves for lubricating, and it is also used for a temporary repair clamp. One jolt of a rusty, squeaky spring may cost you ten times the price of this sure preventive, which is adjustable to any size auto spring. This device is sent prepaid anywhere for $1.50. Send your inquiries and orders to the Spring Leaf Lubricator Co., 1000 Forest Ave., Ann Arbor, Mich.

Tire-Doh for Repairing Tires.

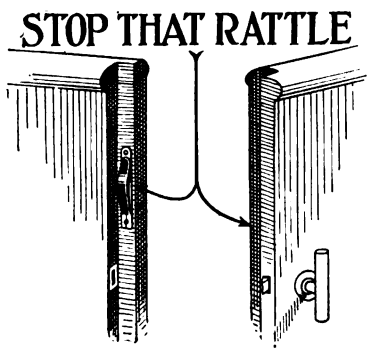
Tire-Doh is so well known to manufacturers throughout the country that it hardly needs exploitation at our hands. The manufacturers state that no matter how big the puncture, blow-out or tear, with Tire-Doh you can repair it in a jiffy. It can be used anywhere, in the garage, or on the road, without heat, without tools, and the cost of repairing the average puncture with Tire-Doh is only 2 cents. This article has been six years on the market, and more than 250,000 car owners are using Tire-Doh while thousands of dealers sell it all over the country. It may be obtained at your dealers, or will be sent direct to you for $1.00. The same manufacturers have 18 other Tire-Doh products including the following: Silver Quick, Stop That Radiator Leaking, Day Tire Valve, Nomore Rust Rim, Paint, Blac-Namel, Sunshine Metal Polish, Everwear Nickel Polish, Metal-Lac, Renew-O Leather Dressing, X-Ray Top Dressing, Nu-Stain Top Lining Dye, Preserv-O Tire Paint, Destroy-O Carbon Remover, Sta-On Engine Paint, See-Kleer, Chemico Blowout Patch, Body Gloss. In regard to Tire-Doh or any of these other articles, write to Atlas Auto Supply Co., 3203 W. Lake St., Chicago, Ill.

A Fine Electric Lantern.

The Lightning Bug Lantern is a modern, portable electric lantern, a handy and economical illuminator which has numerous points of practical excellence in its favor. This lantern is not only practical, strongly made and suitable for either in or outdoor service, but is attractively designed as well, and the exceedingly reasonable price brings it within the reach of all. It is intended for general use around the house, barn, camp, garage and in fact, wherever the oil lantern and flash light have been used, or where a good light is needed. It is clean, convenient and effective, no matches, no danger of fire, and always ready. With its use one can read ordinary print at a distance of 50 feet. The producing of this powerful light from an ordinary single cell battery, is one of the

Lightning Bug Lantern.

greatest accomplishments of modern science, and has been made possible only by the latest development of the Tungsten Electric Filament in connection with a new scientifically designed reflector in this lantern. This achievement which is one of the latest in electrical discoveries makes it possible to obtain a strong, brilliant light from a very low electric current. Their low price and cost to maintain, one battery lasting with ordinary use from six to twelve months, their safety and adaptability to all requirements, under all conditions, is bound to make these lanterns mighty attractive sellers. It is made by the Stewart, Skinner Co., Worcester, Mass.



The C. B. Anti-Door Rattler.

This is a device to stop the rattling of automobile doors, and no doubt the same plan could be applied to windows

Good Anti-Door Rattler.

or movable panels of any kind. The device is placed on the door step with two small screws which are entirely out of the way, and this device also throws the door open when it is unlatched. This Anti-Door Rattler is made of special non-corrosive metals. It is highly polished, and will last a lifetime. It

Same Applied to Automobile Door.

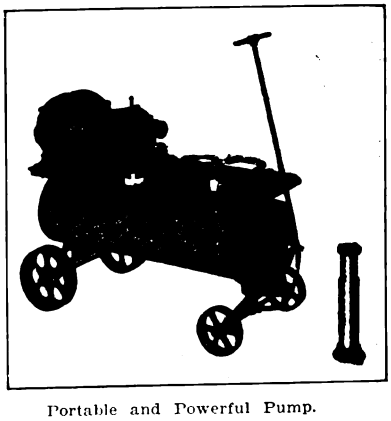
absolutely stops the disagreeable rattling and may be obtained for only 25 cents. The device will be sent post-paid upon receipt of the price to any reader of this magazine. Address all inquiries and orders to William J. Bailey, 401-7 Mulberry St., Newark, N. J.

Something New.

Get Buob & Scheu's 1915 Coyprighted Order Blanks, showing how to order Automobile Top Covers, which consist of roof, quarters, stays, back curtain with celluloid light, welts, etc., which are sewed, finished, made ready to draw on. These covers can be drawn on by anyone without any experience. By buying B. & S. Top Covers, you can save over half the cost of a new top. Then again you can save freight charges. It is customary to send the old frame into the manufacturer, but with these copyrighted order blanks, this is not necessary. If these are filled out with proper measurements, covers can be made that will fit tops for any make of cars. Write for B. & S. 1915 Coyprighted Order Blanks to Buob & Scheu, Court and Broadway, Cincinnati, Ohio.

Valuable U-Sav-Your Products.

U-Sav-Your Dressing for washing automobiles is very highly recommended by all who have used it. The manufacturers state that no one should use soap and water on a motor car,—because if the water is too hot it cracks the varnish, and if too cold it cracks it also. In either event it kills the varnish. You must stop washing your car with water and soap, gasoline and kerosene, but if you simply take a bottle of U-Sav-Your, shake well, put on a piece of cheesecloth, and apply same to all parts of your car, it will astonish you. Why? Because it will remove hard dirt, oil, grease, and

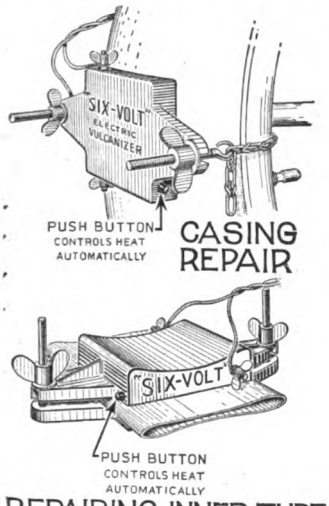


Car Treated With U-Sav-Your Dressing.

tarite immediately without scratching. It will polish the car, not deaden it like alkali, gasoline, kerosene, lye, potash, water, and soaps. It will never gum or catch dust like oil, etc. U-Sav-Your Dressing sells for only 50 cents per bottle. This preparation is not only good for automobiles, but it is a great life restorer for fine woodwork, enamel varnish, brass or leather surfaces of any kind. Send for sample bottle and it will surprise you. The same manufacturers also make U-Sav-Your Tire Remover, for removing Quick Detachable Rim Tires which remove these tires easily and automatically and sells for only $3 delivered in the United States or $3.50 in Canada. Address your orders and inquiries to the U-Sav-Your Manufacturing Co., Warren, Mass.

A New Garage Pump.

The Northern Engineering Works, Detroit, Mich., have placed on the market a new garage pump which differs



Portable and Powerful Pump.

from most others in its unusual power and of course in its range of use. As will be seen it is portable and no first-class garage should be without it.

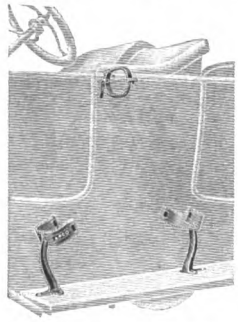
Digitized by Google

A New Electric Vulcanizer.

Motorists generally are rapidly being convinced that the portable vulcanizer designed especially for their use is a very valuable piece of apparatus to possess and when used intelligently, and in accordance with the directions furnished by the manufacturers, it means a material saving in tire expense every year, for with the portable vulcanizer permanent patches can be made on inner-tubes in a very short time and small cuts in casings can be healed before moisture and dampness gets into the fabric of the casing, which causes it to

Showing Method of Using Premier Six-Volt Automatic Electric Vulcanizer.

weaken and rot, blow-outs being an early resultant trouble. The Premier "Six-volt" automatic electric vulcanizer is designed to operate from the regular 6-volt storage battery furnished as regular equipment to all up-to-date motor cars and eliminates the danger from fire resulting from the use of highly inflammable liquid spirits as fuel. Burned or overcured tubes or casings is an absolute impossibility with the Premier "Six-volt" vulcanizer, as the electric current is controlled automatically by the heat temperature of the vulcanizer, and the electric current is automatically cut off or opened the very instant the vulcanizer attains the correct heat to properly vulcanize the repair. Great simplicity of operation is claimed for this new vulcanizer, as there is nothing to do but simply connect the "Six-volt" to your battery, apply it to the tube or casing, and press the button, this pressing of the button completes the electric circuit through the vulcanizer and lets the electric current heat it to the desired temperature to vulcanize rubber, and when it attains this temperature the thermostatic cut-out automatically opens the circuit. The vulcanizer then cools off and is ready for another job, the automatic cut-out being capable of operation several hundred times before becoming exhausted. The "Six-volt" also is very small and compact and less cumbersome than other portable vulcanizers and as it weighs approximately two pounds it is not a burden to carry in the tool compartment but is always ready to put a patch on an inner-tube that "stays put" and to heal cuts in casings while fresh, which means much toward cutting down tire expense. The Premier "Six-volt" is manufactured by the Premier Electric Co., 4038 Ravenswood Ave., who will be glad to furnish circular matter free to all live dealers upon request. This device will repair inner-tubes and casings up to 5 inches in diameter and furnished complete with ten feet of flexible connecting cord, repair gum, cement, scissors, casing tire tool and wax paper ready for use. Price, $3.50.



Brilliant Kerosene Gas Lighting Systems.

The Brilliant Gas Lamp Co., 1009 South Wabash Ave., Chicago, Ill., is marketing a line of lamps and kerosene gas lighting systems which are the outcome of continuous experiments to obtain the exactly right adjustment and combination of parts which would produce a perfectly satisfactory and safe incandescent light of 500 to 1,000 candle power, fully as safe in use as ordinary coal gas illumination, free from all elements of danger and inefficiency and from the grounding or crossing of electric wires. Brilliant Kerosene Gas Lamps are faultless in performance, owing to the absolutely perfect adjustment and combination of every part. They burn common kerosene or coal oil that you can buy at any grocery store. So perfectly is the action of this remarkable burner that it can be in use daily for a whole year and yet will not produce enough carbon and oxide deposits to necessitate the changing of the generator. These lamps are well adapted for lighting public and private garages. Address the manufacturers for prices and full particulars.

New Apco Specialties.

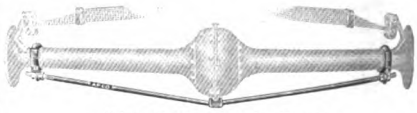
Dealers and the trade stocking for the spring trade will be interested to learn that the Auto Parts Company, Providence, R. I., manufacturers of the well established line of Apco specialties for worth investigating. They are practical and necessary equipment and are sold with the usual liberal Apco guarantee of "satisfaction or your money back."

The Apco side tire holders are designed to be placed on the left hand side the Ford car, has brought out four new devices for this machine which are of the car, a location that makes them

"Apco" Side Tire Holder.

quickly accessible. Another advantage of the side position is that the tail light bracket does not require altering, and a tire trunk can be fitted if desired. No straps are used with the Apco holders. The shape of the holders is such that one or two shoes can be carried without their chafing, and the Apco design will take two 3½-inch tires or one 3-inch and one 3½-inch.

A tire can be removed or replaced in five seconds. A solid brass mail type of lock, having a rubber covered clasp, and which opens automatically when the key is turned, is furnished, but its use is not necessary as the catch locks securely. They weigh but seven pounds, come complete with screws, bolts, etc., and sell for the small sum of $2.

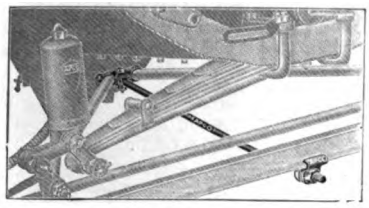


Another new Apco specialty for the Ford car is the spring leaf lubricators. These not only stop all squeaks, but keep the leaves lubricated, making the car ride better and prevent breakage. Each lubricator consists of a pair of plates having oil reservoirs and felt inserts. The inserts are soaked with oil, and resting against the sides of the springs feed the lubricant by capillary action.

"Apco" Spring Leaf Lubricator.

The frictional surfaces are thus automatically lubricated and without attention. The maker calls attention to the design of the Apco lubricators, stating that it is the only type that lubricates both sides of the spring. They are attached in a few minutes with a screw driver and a small wrench, and a set includes four pairs, two pairs for each spring. Each plate, which is of semi-steel, has an oil cup for renewing the supply of lubricant. The Apco lubricators sell for $2 the set of four pairs.

After much experimentation and tests the Auto Parts Company has perfected



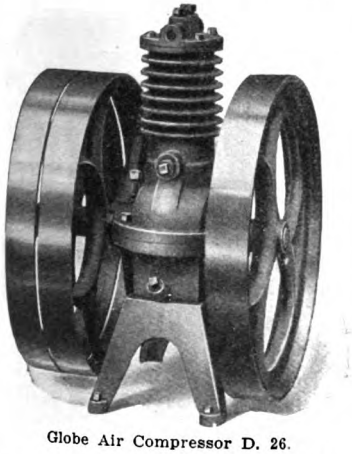
"Apco" Rear Axle Truss.

a rear axle truss that can be fitted in 10 minutes with an ordinary wrench. The Apco truss is designed for cars made previous to 1915 although it is a practical device for the latest models as it greatly strengthens the rear axle. The Apco rear axle truss is not only adjustable, but will prevent leakage of lubricant from the differential and eliminate noisy operation of gears caused by a sagging housing. The price complete is $1.50.

The front radius rod of the Ford car is utilized to maintain the front axle parallel with the motor and to prevent it moving backward when an obstruction in the road is encountered. As it is constructed of tubing there is more or less spring or give to it which allows the axle to tip backward affecting the steering the car. To overcome this trouble and to improve the operation of the radius rod the Auto Parts Company, Providence, R. I., has perfected a simple and ingenious front axle brace. It consists of a half-inch steel rod and two novel clamps. One of these clamps is

Digitized by Google

attached to the V of the radius rod by three bolts and these bolts and the end of the rod have square heads which prevent their turning. The square head of the rod is integral with it. The other clamp is made in two sections and is secured to the front of the axle by bolts

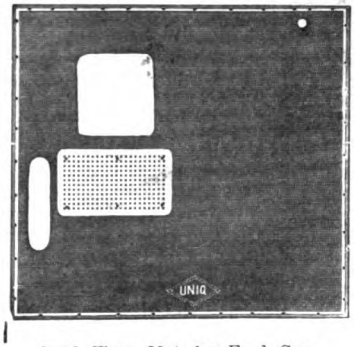


"Apco" Front Axle Brace.

which pass through both havles. Anyone can fit the brace in five minutes with a wrench. The Apco brace comes finished in black enamel, and weights but three pounds. It lists for $1.50.

The Globe Single Stage Compressor.

This new compressor has several desirable features in addition to its attractive price. Every bearing, including piston end of connecting rod, is adjustable to take up wear and the provision for such adjustment is more convenient than in any other type of compressor with which we are acquainted. For instance, to take up the main crank shaft bearing it is only necessary to loosen a single lock nut, adjust a single set



Globe Air Compressor D. 26.

screw and retighten the lock nut. Many of the garage compressors on the market have no provision at all for taking up even the crank shaft bearings, so that when the bearing becomes worn slightly, the compressor either goes on pounding or a new bushing must be substituted. The compressor valves, which are hardened tool steel, are arranged for vacuum, as well as pressure. The intake valve is tapped for pipe connection to a vacuum tank, so that anyone having one of these compressors can use same for both vacuum and pressure without making any alterations. This is a particularly valuable feature when used in a tire repair shop as the vacuum tank can be used to deflate inner tubes, saving much time over the old way of rolling the air out by hand. Equipment D 26 herewith illustrated retails for $25.00. For particulars regarding this and other types of compressor, address the Globe Manufacturing Co., Battle Creek, Mich.

The "Uniq" Floor Mat for Ford Cars.

This floor mat is made of genuine heavy cork linoleum, and has a wire edging covered with aluminum or brass molding which keeps the edges of the mat perfectly flat without screwing or nailing it to the floor boards. An aluminum pyramid heelplate is securely attached to the mat just below the pedal opening where the heels usually wear holes in an ordinary mat. This mat is made especially to fit the Ford car and has the regulation openings for pedals, shifting lever and speedometer shaft

Good Floor Mat for Ford Cars.

tube. It is extremely durable and is very neat in appearance. It is made in grey or brown colors to match the "Uniq" running boards. The price of this mat ready for use is $2.50 with aluminum binding or $3 for brass binding. The same manufacturers are making complete running boards for Ford cars, also Ford valve grinders, combination valve tool for Ford engines and other specialties for the Ford car. Address all inquiries and orders to the C. Spiro Mfg. Co., 68 East 131st St., New York City.

A Good Ford Fan Belt.

The No-Slip, No-Stretch Ford Fan Belt here shown is made of a strong nelastic fabric, having a ply of chrome eather sewed on the inside where it omes in contact with the pulleys. The whole belt is treated by a special pro-

A Good Ford Fan Belt.

cess which makes it waterproof and gives the leather a rubber-like finish, which makes it hold perfectly to the pulleys without the use of belt-dressing. These belts give long wear and will not stretch out. They retail for 40 cents each and are made by the Leather Tire Goods Co., Niagara Falls, N. Y.

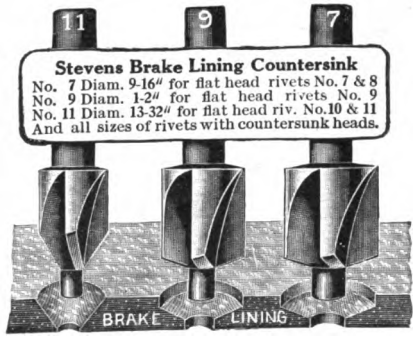
Opco Carbon Remover.

Something over a year ago an expert in lubricating and volatile oils conceived the idea of eliminating carbon trouble by a chemical process having an oil base

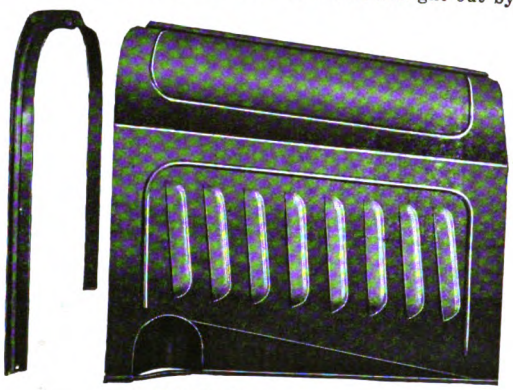


For Removing Carbon.

and applied in such a manner as to reach every part of the motor itself. After a series of tests, covering a period of several months, the question was solved and not only resulted in removing severe cases of carbon trouble by a single application and preventing a recurrence of the same by the use of a small quantity once a week, but also had the advantage of increasing the efficiency of the motor by cleaning and lubricating every working part of the motor itself. These facts are testified to by well-known and acknowledged experts and users. Opco carbon remover is the formula of oil experts. There is nothing in the cylinder cleaner to injure any part of the engine, as it is absolutely harmless to everything except carbon, which is destroys, It penetrates, softens and completely removes carbon, and it is easily introduced through spark plug taps. A large cam containing sufficient to clean 16 cylinders sells for $1. This product is manufactured by the American Oil Products Co., Inc., Buffalo, New York, to whom all inquiries should be addressed.

Stevens Brake Lining Countersink.

This is an extremely well made tool and it is handy in any repair shop or garage for countersinking the brake



Tells its Own Story.

lining for attachment to the car. The inscription on the accompanying cut shows the various sizes of these countersinks and prices and full information concerning them will be furnished to our readers by the manufacturers, Stevens & Company, 375 Broadway, New York.

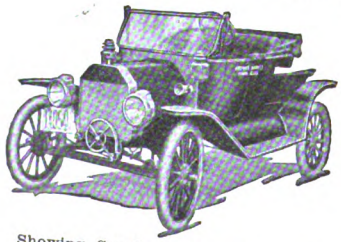
Sloping Hood for Ford Cars.



The Livingston Radiator and Mfg. Company, of Amsterdam Ave. and 75th St., New York, have recently announced a sloping hood for Ford cars. This hood adds to the appearance and beauty of a Ford car, by giving it a long streamline effect, and is made of No. 20 B. & S. gauge steel, finished in black enamel. It is constructed with vents or fins on the sides, so as to allow the heat generated from the motor to escape from under the hood. It is easily attached to the Ford car, as a hood ledge is furnished free with each sloping hood. The hood hooks used as regular equipment of a Ford car fit this new hood, making it absolutely interchangeable with any hood on any Ford car. It is made to fit any Ford type of radiator, but in conjunction with the Livingston Pointed Front radiator it gives the Ford car a distinctive and individual appearance. It is listed at the extremely low price of $8, and is sold by dealers generally throughout the country. This bonnet is finished in the same complete way that have made Livingston radiators so popular with the drivers of Ford automobiles. As these bonnets are packed in pasteboard cartons they can be shipped by parcels post.

New Hood for Ford Cars.

The Sandbo Starter.

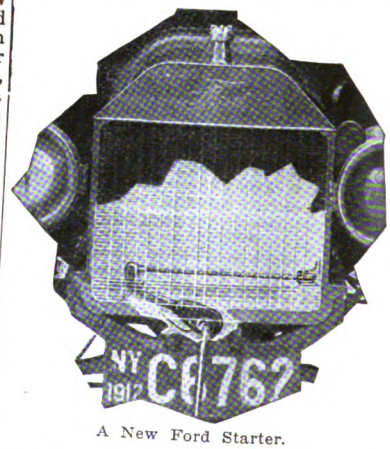
This is a mechanical pull starter, operated by means of a cable from the seat, and the manufacturers state that it is the only Two Compression starter on the market. A polished handle fits in a neat socket in the dash. From this the cable leads under the hood, over a pulley to the odd shaped wheel in front of the radiator. This wheel is nickel plated and an ornament to any car. One sharp pull of the cable turns the crank a complete revolution and over two compressions and past two ignition points. This system insures a quick and satisfactory starting of the car. The Sandbo Starter which is manufactured at Rock Island, Ill., is handled in New York by the Star Rubber Tire Co., 1781 Broadway, and we understand that a great many New York manufacturers are installing this device.

Showing Sandbo Starter Attached.

A Booklet of Allen Specialties.

Every motorist or dealer who reads this magazine is likely to be interested in a very attractive booklet which has just been brought out by the Allen Auto Specialty Company, 1926 Broadway, New York City. This booklet describes and illustrates the well known line of Allen tire cases, also the Allen Tyrometer, or tire pressure gauge, Allen tire locks, radiator covers, blue book covers, and a long list of other useful and attractive automobile specialties. We understand that this booklet will be sent free for the asking to any of our readers.

Superior Hood for Ford Cars.

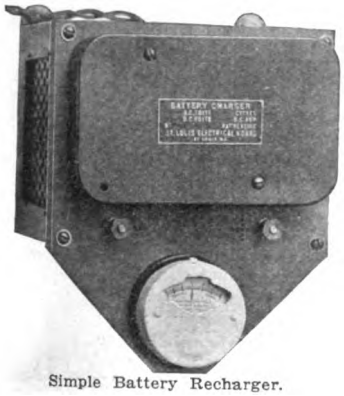


This is a new Stream-Line hood which has been brought out especially for the Ford car by removing the old hood rest and screwing on the new one. This new hood is set on the car and your Ford is completely changed in appearance. The tapered Stream-Line of this hood produces longer up-to-date lines for the whole car. This hood is built solidly and substantially and will not rattle or creak. It tapers to the top of the wood dashboard, also tapers on both sides and has a separate hood rest ready to screw on the dash. There are no exposed hinges on the top and the old hood hooks fit the new hood perfectly and snugly. This hood has six ventilator grills raised on each side allowing the heated air pr duced by the motor to escape. This fe ture can be appreciated in warm weath and it is claimed that the cooling improved 100 per cent. on this accoun This hood is sold complete ready to a tach for only $11.40 and many Ford ow ers will undoubtedly be interested in i This is also a big proposition for deal ers. Write for full particulars to th Superior Lamp Mfg. Co., 136 West 52n St., New York City. The same com pany manufactures a V Type radiato for the Ford car and they will allow $ to any Ford owner on his old radiato regardless of its condition.

Stream-Line Hood for Ford Cars.

Robertson's Pres-Toe Ford Starter.

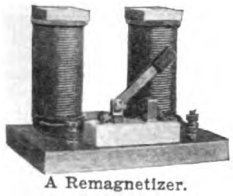
Described as a starter that places the Ford in the $5,000 class and a starter that the ladies can operate, Pres-Toe starter is a mechanical device operated by a lever, pressed by the toe. Pres-Toe Starters are the result of several years experimenting by the manufacturers to produce a reliable, serviceable and easy to operate method of starting the motor from the seat. All these features have been accomplished in the Pres-Toe Starter. By actual test Pres-Toe starters have proven 100 per cent. efficiency. A novel test was recently indulged in to cross a stream 16 inches deep 100 times, stopping the motor in the center. The motor started every time on the first attempt. The impelling unit is a very ingenious part, constructed entirely of high grade hardened steel with full ball bearings running on hardened ground steel cones, thereby placing the device on an almost never wear out basis. In the impelling feature noisy ratchet teeth are entirely eliminated. A ball and socket joint is used which is positive and all danger of broken teeth dispensed with. Pres-Toe starter is provided with an automatic release to eliminate all dangers from back firing of the motor. The entire system is installed under the hood, even the original starting crank is left in place. To install the Pres-Toe starter no holes are drilled or the present arrangement disturbed and with the instructions attached to each starter any owner can install it perfectly with his present outfit of tools. No driver of a Ford car can appreciate the extreme pleasure and convenience that is attained by the Pres-Toe starter until he has one installed. Pres-Toe starters will save the cost of installation



A New Ford Starter.

Digitized by Google

in a very short time through the saving of gas and oil consumed by the motor running while standing, as many drivers do rather than get out and crank. What is more annoying to a driver than to have to get out and crank a stalled motor in a busy thoroughfare? With Pres-Toe Starter installed you are wise, press the toe and away you go. Write to-day to the manufacturer, W. Robertson, 32 Greenwood Place, Buffalo, N. Y.



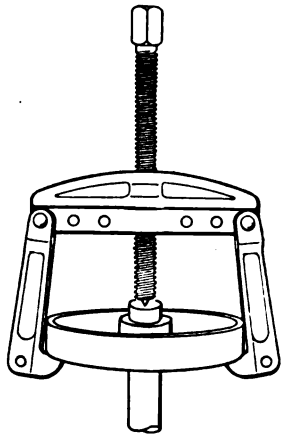
A New Battery Recharger.

The St. Louis Electrical Works, Arlington and Easton Aves., St. Louis, Mo., are making a battery recharger or rectifier of a simple and inexpensive type. It is convenient to use, simple to operate, small and light. It will charge a dead battery in the proper direction and is designed to operate on circuits of a wide variation. It is guaranteed free from all mechanical or other defects for

Simple Battery Recharger.

a period of one year. A different size is made for different kinds of work and those interested would do well to send for a booklet which the company issues and which describes these chargers and

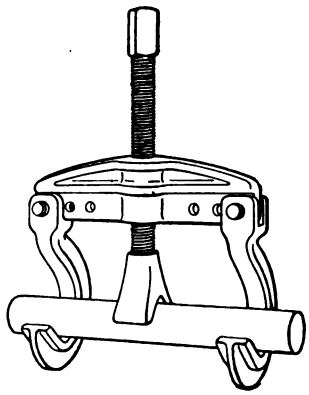
A Remagnetizer.



likewise a magnetizer. They are both useful in a garage or for private use.

Bethlehem Steel Back of Silvex.

It is important that the consumer as well as the dealer can depend upon the manufacturer back of a product. In this respect the Silvex Company holds a unique position in the automobile accessory business. Rumors have been current from time to time as to the backing of this company. All doubts have now been set at rest on this point by a recent statement from Mr. J. W. Fischer, vice-president and sales manager of this company. Mr. Fischer states: "We are endeavoring to acquaint both the automobile owner and the dealer—the jobber has already been posted and knows—with the fact that the Silvex Company is headed by Mr. Chas. M. Schwab, president of the Bethlehem Steel Company, a man head and shoulders over anybody connected with the steel industry. Our goods are manufactured at South Bethlehem, Pa., the mecca of all skilled mechanics in the metal working trade. The name 'Bethlehem' on any product is an absolute guarantee as to mechanical skill, workmanship and quality. There are but few automobile accessories with such a standing before the consuming public as that of the Bethlehem Five Point Spark Plug."



New Model Crane Wheel and Gear Puller

This device which we illustrate herewith is an extremely handy tool in any

Showing Use of Crane Puller.

garage or repair shop, and the cuts herewith shown serve to illustrate the uses to which this tool can be put. The line of work done by the Crane Puller includes removing automobile wheels, flywheels, transmission and cam shaft gears, commutators, sprockets, collars, couplings, etc., and there are various attachments which render it possible to do a great variety of work. One of the illustrations shows the pipe bending and shaft straightening attachment so clearly that an explanation is hardly necessary, and the other cut shows the method of removing a pulley from the end of a

Pipe Bending and Shaft Strengthening Attachment.

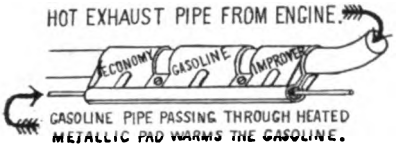
shaft. For heavy work a three arm puller is made by the same manufacturers, and there are also extension arms provided for work beyond the reach of one set of arms. The Crane Puller is put out under an unusually strong guarantee. If one of these tools is broken on any legitimate work, the broken parts may be returned express paid with a description of the way it was broken, and another puller will be sent absolutely free of charge. This amounts to a complete guarantee against any defect in workmanship, and it shows that the manufacturers have made an exhausted study as to the material and method of construction in making this remarkably strong application. This apparatus ought to interest every repairman in the country and any who may be interested are urged to write for full description and price lists to the Crane Puller Co., 54 Lake Street, Arlington, Mass.

Eklips Spark Plugs.

This is a new line of spark plugs which has just been placed on the mar-

The "Eklips" Plug.

ket by The Fulton Company of Milwaukee, manufacturers of the well known Aermore Exhaust Horn. The Eklips plugs have many new and ingenious features to keep them free from oil and soot, and it is claimed by the manufacturers that they give more power with less gas. Four types are put out in porcelain insulation listing at $1.25, $1, 75 cents, and 50 cents, and two Mica types are listed at $1.25 and $1. These plugs are made in all sizes for automobiles, motorcycles, and motorboats by The Fulton Company, 726 National Ave., Milwaukee, Wis. Write for full particulars.



Veedol for Lubrication.

The life and efficiency of the car is dependent largely on the lubrication. The manufacturers of Veedol are anxious to get before our readers the facts in regard to this excellent lubricating medium, and they want as many of our subscribers as possible to write for the Veedol book on automobile lubrication, which will be sent free upon request. Veedol is to be extensively advertised, and it makes an excellent article for dealers to handle, and dealers throughout the country before they buy any more oil should see the Veedol salesmen. Dealers are requested to write for the special portfolio describing the advertising campaign which the manufacturers of Veedol have inaugurated for 1915. All communications should be addressed to the Platt & Washburn Refining Company, 20 Broadway, New York City.

The Economy Gasoline Improver.

This is a device for warming the fuel supply on Ford and other automobiles, and the method of applying the invention is well illustrated in the engraving which accompanies this article. The gasoline is warmed by a heated metallic pad, through which a gasoline pipe is passed, and the heat is furnished from the exhaust pipe of the engine. The device clamps over the exhaust pipe and around the gasoline feed line from the outside of the exhaust pipe, and is conducted through the walls of the cylindrical chamber, which is filled with a soft metallic pad, thus thoroughly warming the fuel supply. The Economy Gasoline Improver can be attached to a Ford car in ten minutes by any one, and it is claimed by the manufacturers that it increases the power of the engine materially, gives a large increase in miles per gallon, decreases the accumulation of carbon, and adds greatly to the smooth running qualifications of the motor. The cost of the apparatus complete is $2.35, and it is manufactured by the Inst Lighter Company, No. 58 E. Main Street, Columbus, Ohio, to whom all inquiries should be addressed.

Showing How Fuel Supply is Warmed.

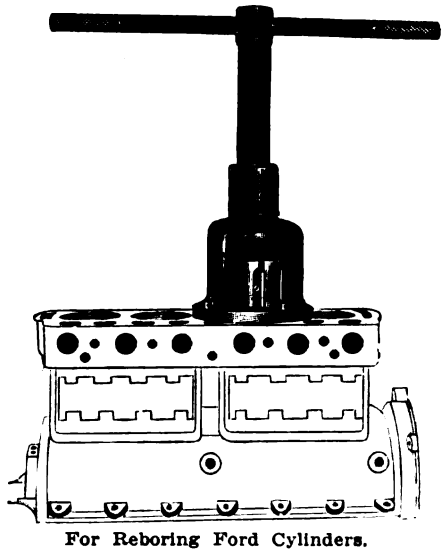
Prize Offered by Rajah Auto Supply Company.

In connection with the forthcoming Vanderbilt Cup and Grand Prize Races, the Rajah Auto Supply Company, of Bloomfield, N. J., manufacturers of the Rajah Spark Plugs, are offering a prize of three hundred dollars in gold to the driver making the best time for the first hundred miles of the Grand Prize Race. This is a sporting proposition on the part of the Rajah Company, as no restrictions are placed on the car being equipped with their product. Heretofore, almost all accessory prizes have been contingent upon the car using the product of the manufacturer who offers the prize, but in this case there is no such restriction.

Electric Starters and Batteries Repaired.

Neither the car owner, nor the average garage owner understands repairing electric starters and batteries, but the work is done and done well by the Electric Self Starter Repair Company, 244 West 49th Street, New York City. They absolutely guarantee all their work and they repair not only electric starters and batteries of all kinds but coils and magnetos and they also rewire motors when this is required. They have experienced battery and starter repairmen who were formerly connected with the Packard Company. Readers who are interested should send in their orders and they may be assured of satisfactory results.

New Agent for Republic Tires.



William M. Perrett has been chosen branch manager at Detroit, Mich., for the Republic Rubber Company at Youngstown, Ohio. Mr. Perrett is a veteran in the tire business by virtue of 20 years actual service, and is exceptionally well equipped for his new post. Mr. Perrett is very prominent in Masonic circles, at present being Grand Master for the State of Michigan, and also past potentate of the Shriners at Detroit. Mr. Parrett's headquarters as branch manager of the Republic Rubber Company will be at 1001 Woodward Avenue, Detroit.

"Blitz-Blank," the Magic Glass Cleaner.

Many accidents could be avoided if the driver of an automobile could always be sure of a clean windshield. "Blitz-Blank" is a preparation for cleaning glass which is of such excellence, that it may well be called, "the magic glass cleaner." When applied to the windshield, it positively prevents frosting, steaming, or smearing caused by moisture, dust, grease, change of temperature or rain. It sheds the rain quickly and evenly from the windshield and insures to the driver a clear vision and an effective safeguard against accidents. It is always ready for instant use, is non-injurious and can be easily applied. It sells for 25 cents and should be carried in the stock of every dealer as it is a great seller. To dealers, an attractive display card is offered and so low a price on the goods that it affords an excellent profit. For full particulars, address the manufacturers, The Utility Mfg. Co., 6 East Lake Street, Chicago, Ill.

The Davis Cylinder Reboring Jig and Reamer.

This is a special tool for reboring Ford cylinders, and the manner in which it is used is well indicated by the illustration. The Ford Company furnishes pistons, one thirty-second of an inch over size, and the tool here illustrated rebores cylinders to fit these special pistons; and it is claimed by some, that after the cylinders are thus rebored, the motor is even better than when new, because it is claimed that old cylinders which have seen months of alternate expansion and contraction are seasoned out, and are far superior to new castings. One man can rebore a set of four cylinders in sixty minutes with this machine. The tool centers itself, and an inexperienced man can do as good a job as an expert machinist. With this tool the smaller shops and garages can rebore cylinders and guarantee the work to be as good as the larger dealers with their expensive machinery. Readers who are interested should write to the Hinckley Machine Works, Hinckley, Ill. They manufacture this device, and will gladly quote prices, and give all information concerning this handy tool.

For Reboring Ford Cylinders.

Gasolette.

This is a new product which it is claimed, will increase the power of the motor, through the lessening of gasoline consumption. It is being placed on the market by Bergman Bros., No. 1777 Broadway, New York City, and this same concern is factory representative of the Auto Parts Company of Providence, Culver, Stearns Mfg. Company of Worcester, Mass., and Marvel Auto Supply Co., of Cleveland, Ohio. They state that it is an article of exceptional merit, which will, no doubt, become well known to the accessory trade.

The Bosch-Ford Attachment.

The manufacturers state that the newest Bosch-Ford Attachment is an efficiency promoter, as it makes possible an easy and mechanically correct installation of the Bosch Magneto on Fords, and results in a positive betterment of the car; gives more power, more speed and more economy, and, due to even and positive ignition, reduces the wear on the engine and the car in general. The magneto used with this outfit is a Bosch Magneto, the same quality which goes into the highest class of automobile, and the few fittings which are necessary are also made in the Bosch factories. This Bosch-Ford Attachment offers an especially attractive proposition to dealers, and many readers who sell automobile accessories will wish to take advantage of this opportunity to handle a good seller. Stock a few of these attachments now and your orders will have prompt attention and be shipped by a nearby supply station. A Bosch-Ford book will be sent on request by any who will take the trouble to ask for it. Address all inquiries and orders to the Bosch Magneto Company, 202 West 46th Street, New York City.

Marathon Tires.

These tires are built entirely by hand, of the finest materials obtainable, and they are vulcanized by the unit-cure wrapped-tread method. To the dealer who is desirous of securing the better class of trade the agency for these tires represents a good business opportunity. Write for exclusive agency proposition by which the dealer controls his own territory. Your inquiry will bring you full particulars as to selling plan and co-operation with the dealer. Address all inquiries to the Marathon Tire & Rubber Co., Cuyahoga Falls, Ohio.

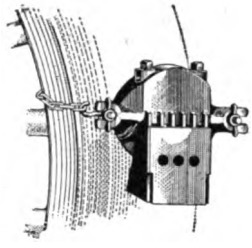
"WIZARD" AND "G WIZ"

STEAM VULCANIZERS

WILL CUT YOUR TIRE EXPENSE IN HALF

HOW TO GET MORE MILES OUT OF YOUR TIRES: You lose thousands of tire miles by not keeping them properly inflated; by applying brakes too quickly, by rubbing against curb stones, by letting car set on oily floors, etc. However, the greatest abuse is to **neglect those small cuts in casings.** Layers of fabric supply strength to the tire, and the rubber covering is to protect them. Small cuts expose the fabric to water and sand, forming sand blisters and rotting the fabric. A blowout at the weakened spot is the sure result. Keep those cuts vulcanized and your tire will last until the rubber tread is worn off all the way around, giving you double the usual mileage.

WHICH IS THE BEST VULCANIZER FOR YOU? The fact that we are the oldest and largest manufacturer of portable steam vulcanizers in the world should mean a lot to you in deciding. Our vulcanizers have been adopted by the U. S. and many foreign governments, and are recommended by the large tire factories. We use **steam heat** in all our machines. **Steam** will not burn or overcure the tire. **Steam** is used by **all** tire makers and large repair shops **exclusively.** Our long experience and large factory facilities guarantee you a better vulcanizer for less money than you can get elsewhere. If you do not find it so, send it back and get your money.

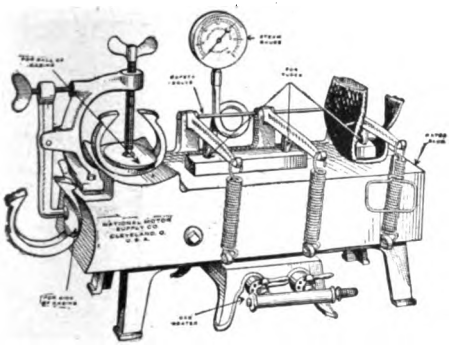


WIZARD Automatic Steam Vulcanizer

For both tubes and casings of any size. Burns gasoline with no smoke and no flame exposed. Requires no watching, as heat is automatically controlled. Water put in at factory and never needs refilling. Steam is the only safe method of vulcanizing. Vulcanizing surface 3″x6″, curved for casings and clamps against plate for tubes. Highly polished and nickel plated all over. Insulated handle. Weight six pounds. It has saved thousands of dollars for our customers. No experience required to use it.

PRICE, With Instructions and All Supplies by Mail, Prepaid, $3.50

Order to-day and save those tires.



G-WIZ Automatic Steam Vulcanizer

For both tubes and casings 3½″ or smaller. Works like Wizard in every way, the only difference being that it is made for small tires. Guaranteed to do perfect work. Thousands of satisfied users. Saves its cost in repairing one tire, and will last forever. Weight 3 lbs.

PRICE, With Instructions and All Supplies by Mail, Prepaid, $1.80

10 DAYS' FREE TRIAL! After you have tried any of our vulcanizers ten days, if not entirely satisfied, return, get your money.

GARAGE AND REPAIR MEN, LOOK!

Thousands of garagemen all over the world are making big profits with our

National Garage Steam Vulcanizer

Vulcanizes three tubes and two casings at a time. Heated by either gas or gasoline. We have made this machine without any change for six years, which shows how satisfactory it is. You might as well have the big profits for vulcanizing in your vicinity. The National is the easiest and cheapest machine to operate on the market.

Combined Horn and Fan.

Credit is given an Indianapolis company for producing what is called the Oakes-Beartone, a combination of horn and fan. Beartone is being marketed for the Ford cars. The Oakes Company is an old one, having been in the metal stamping business for some time, and especially having been manufacturers of automobile motor fans. The builders of the Continental Motor build motors for 128 cars and trucks, and the Oakes is used as standard equipment on Continental motors, besides many other motors.

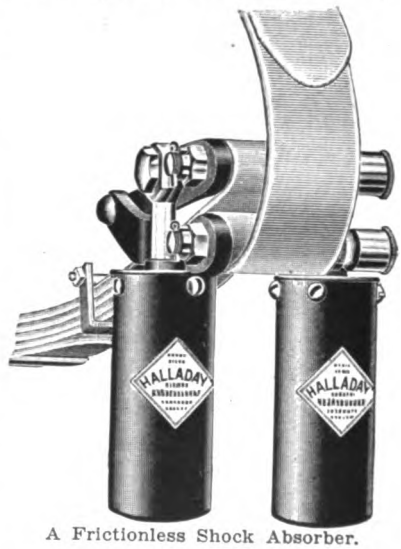
The Bartine Fan.

Because of their fan success the Oakes Company was the logical manufacturers to sponsor the combination of fan and horn. This Oakes Beartone horn has no trumpet. It is operated by attaching a button at the driver's seat, and the driver can regulate the volume of sound and its range by the pressure upon this button. The advantages of the Beartone are said to be many. In the first place, the owner has a fan that does not have to be replaced, but is capable of long wear. The horn being an integral part of the fan, eliminates complicated mechanism. The theory of the Beartone is that the driver of a car never needs to use his horn, except when the motor is running, and whenever the motor is running the fan is revolving, and whenever the fan is revolving by a pressure of the button at the driver's seat a signal can always be obtained from this fan and horn combined.

Gearless Differentials.

Technical writers and automobile engineers have long acknowledged the drawbacks of gear differentials, either of the bevel or spur-pinion types, but since differential action is considered essential to a motor car, the disadvantages have been accepted as necessary evils. Several unorthodox types have been built in the form of worm gears, chain mechanisms, slipping and over-running clutches, which for the most part have had the defects which have kept them from general adoption. There is now, however, upon the market a device which not only has overcome the drawbacks of the usual balance gear, but which seems to have overcome the difficulties experienced with former substitutes for the gear differential. This is the latest development of the Gearless Differential Company, Detroit, U. S. A. The new mechanism takes the place of the gear differential at the center of the rear axle, and in the case of the model "T" size can be substituted in a Ford rear axle without in any way altering the axle housing, ring gear, shafts or bearings. The claims of superiority over the gear differential are numerous, and are substantiated by the testimony of many prominent users, who say that this device does all, and more, than is claimed for it, and serves to prove that "cars are safer to drive." Some very strong claims are made for this device as to its strength and efficiency over the differential gear. A positive drive to both rear wheels is transmitted, therefore one rear wheel cannot spin on a slippery surface and the other stand still. Dangerous skids are eliminated, and a Ford car has a positive service brake on both rear wheels, regardless of road conditions. There being no sideways at high speed, the danger of overturning is greatly diminished. A saving of fuel and tires is effected by absence of slippage, acceleration when one wheel is thrown from the ground, and tendency of back wheels to get out of line (using power to bring them back), also the driving on the wheel traveling the shortest distance, all mean less revolutions of the motor, thus an actual saving in fuel and wear on tires of about 25 per cent.

Imperial Oxy-Acetylene Equipment.



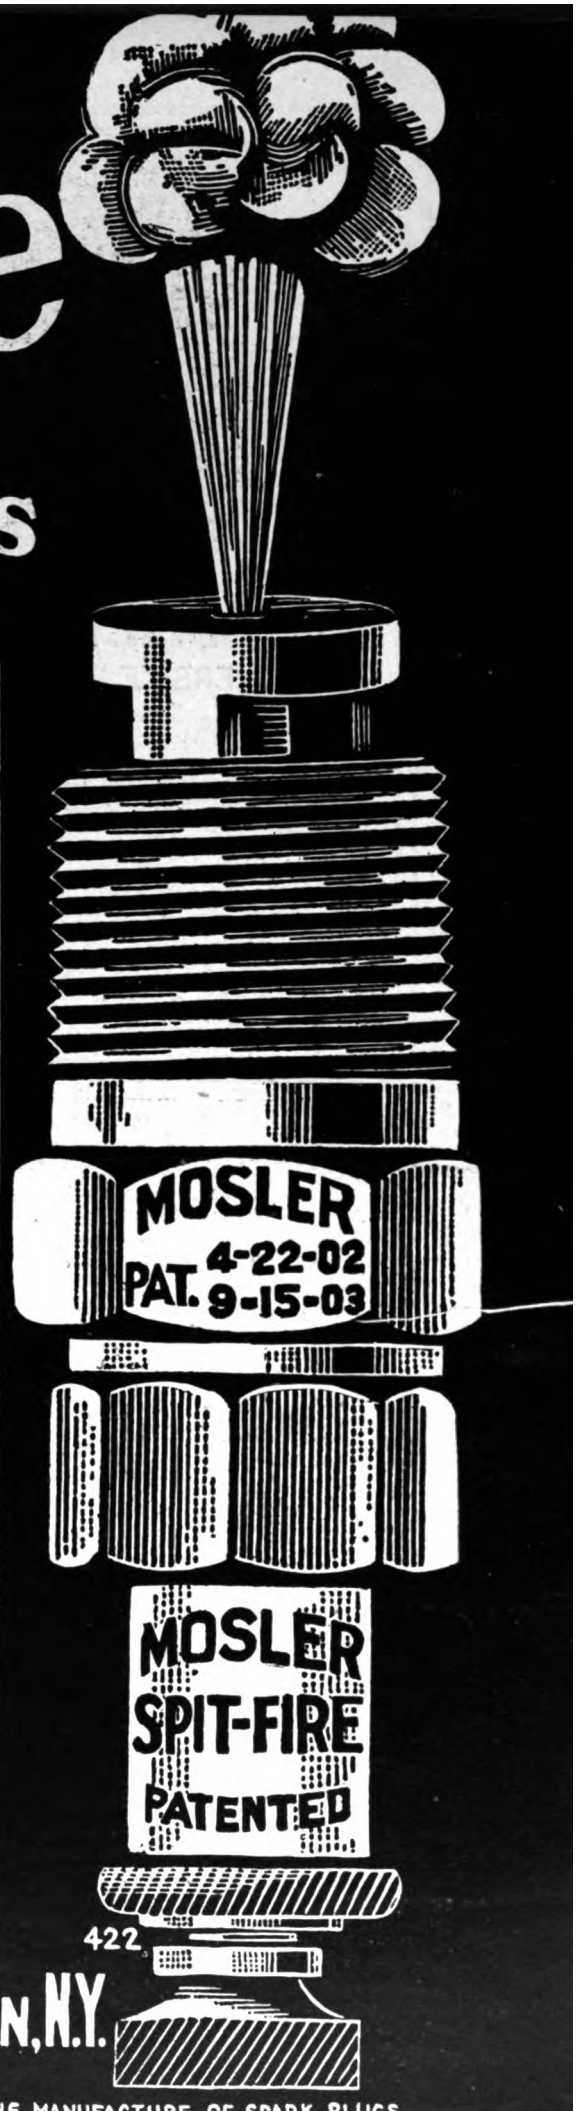
An oxy-acetylene welding and cutting equipment possessing some new exclusive features has recently been placed on the market by the Imperial Brass Mfg. Co., Harrison and Racine Aves., Chicago. Two vital points necessary to safe, efficient, economical and continuous operation of oxy-acetylene equipment are: 1—Thorough and uniform mixing of the two gases employed. This can be accomplished only by designs that are scientifically and mechanically correct and extremely careful and accurate workmanship and properly selected materials in the manufacture of the various parts involved. 2—Close and accurate regulation of both volume and velocity of the gases delivered to the mixing chamber of the torch and ability to maintain a constant fixed pressure under continuous operating conditions as well as to control a wide range of pressures called for by the various requirements of service. The great importance of these two points will be fully appreciated when it is realized that the safety and efficiency of operation and the life of the equipment are directly dependent upon them, as their successful solution eliminates danger of back-firing, undue consumption of gases and burning of tips. The superiority of Imperial equipment, aside from highest quality of materials and workmanship, is largely due to a new exclusive principle fully protected by numerous patents pending, by which the oxygen is mixed with the acetylene to a degree of uniformity not accomplished with any other method. For full particulars address the manufacturers as above.

Cray Tops for Ford Cars.

A special opportunity for dealers is offered in a line of Ford tops now being placed on the market by Cray Brothers, 1119 West 11th St., Cleveland, Ohio. This line gives the dealer or repair man an opportunity to make a great deal of extra money. The Cray line of tops is sold to dealers on exceptionally favorable terms, and the line is of unusual merit, as may be judged by consulting the advertisement from this company in the present issue. The Cray Ford one-man top is described as the most easily operated one-man top made, and the Cray Ford extension top has many special features which commend it to the Ford owner. Cray Brothers publish a free book to auto repair men which they will be glad to send on request to any of our readers who are in the trade. This book consists of 512 pages of bargains, about 8,000 illustrations, and it is a complete auto repairers' guide and price maker, quoting the latest wholesale prices on first quality automobile supplies and accessories of every description. To obtain this valuable book it is necessary to identify yourself as a dealer, automobile repairer or garage owner, and also to fill out and sign the coupon attached to the full page advertisement of Cray Bros. appearing in this issue of our magazine.

The Halladay Shock Absorber.

These shock absorbers are frictionless and are designed for all makes of cars, for three-quarter or full elliptic trucks.



A Frictionless Shock Absorber.

They are fully guaranteed and no grease need be used for their lubrication. They will add to the life of the car and likewise to the enjoyment of riding in it. It is claimed that there is a saving in tires. They are quickly attached and there is nothing to rattle loose and nothing to be adjusted. The price is low, considering their high quality and construction, as well as their elimination of shock. They are manufactured by H. P. Halladay Co., Streator, Ill.

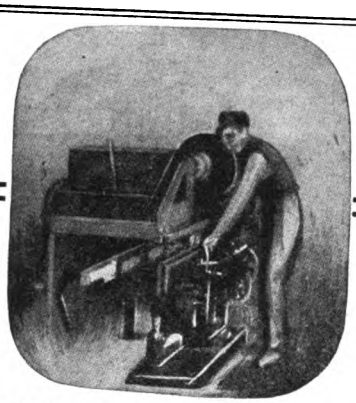
Mosler SpitFire Plugs

Let Mosler Spark Plugs Put More Money in Your Pocket

Every time you sell a Mosler Spark Plug you make a ***real*** profit—and you make a friend, too. Don't miss the chance of making both—stock up now on

SPITFIRE *and* VESUVIUS

These two brands will be advertised to the consumer in big, smashing, selling style, through the 1915 season. It's going to be easier than ever to sell Mosler Plugs—and that means more profitable.



Write *now* for our proposition and be ready!

(Ask for Mosler's Spark-Plug Chart—it shows the right kind, type and size to get the best result out of every car—free on request.)

A. R. MOSLER & CO., P.O. BOX "M" MT. VERNON, N.Y.

WE OWN THE LARGEST FACTORY IN THE WORLD DEVOTED EXCLUSIVELY TO THE MANUFACTURE OF SPARK PLUGS

CYLINDER REGRINDING
AND OVERSIZE PISTONS AND RINGS

High Grade Work Guaranteed

Cylinders ground perfectly straight on a HEALD GRINDER and guaranteed that there will not be more than 1-2000 of an inch variation in a set of cylinders, and the same close work will apply on the pistons.

Piston rings made to fit perfectly, every set ground round specially for each job.

Our Slogan is QUALITY

Write for estimates and state number of cylinders and bore diametors.

OXY-CARBI CO.
396 GEORGE STREET NEW HAVEN, CONN.

An Aid to Starting

Take a small bottle or tin with a little gaso in it and place it for a few minutes in hot w until the gasoline is hot, then place a few drop the hot gasoline in the compression tap and in into the cylinder. This method has been a hel starting. It may be useful to know this as th is no possible danger with it.

Real Platinum Points.

From W. F. Wooster, Washington.—If somec complains to you of faulty ignition through a make of master vibrator tell them to have so jeweler put on some real platinum contacts. solved much of my trouble with a 1913 model Ford in this way. If you think it worth while will explain to any one just how to do the work.

Testing the Compression.

When a cylinder fails to hold compression it is n always easy to tell whether leakage is taking pla past the valves, etc., or past the piston rings. the breather, or crank case compression releas pipe, is examined when the engine is pulled ove compression when hot, it will be found that at eac compression stroke oily gas will be blown out of th breather pipe if the leak is past the piston. It i obviously of no use making this test when the en gine is cold.

A New Dixon Booklet.

In a sixteen-page booklet, descriptive of Dixon's Graphite Automobile Lubricants, the first four pages are devoted to a brief but pointed address to those interested in graphite lubrication. Following this is an individual description of the members of the Dixon Lubricant family. A distinct feature of this description and one that lifts it from the ordinary is the use of a series of well drawn pen-and-ink sketches. The last few pages contain, in detail, recommendations for the use of each lubricant. Altogether this booklet is worth writing for and a request is all that's required by the Joseph Dixon Crucible Company, Jersey City, N. J.

C. P. Valve Lifter.

This is a good tool which the manufacturers state works like a vise, and holds like a vise. It holds the spring rigid, and can be used on any car. The price of this valve lifter is $1, by mail. Send your orders and inquiries to Clinton Machine Works, 460 High St., Clinton, Mass.

The Tuthill Springs.

It may not be generally known that one of the most difficult things to construct for an automobile is the springs. To secure a spring that under all conditions of load and road will answer the purpose, is something not as easy as may be imagined. Then the question of breaking is an important one. Some springs break in the center and some on the ends, but probably 75 out of 100 are liable to center breakage. In the Tuthill spring there is no center bolt whatever. The Tuthill Titanic springs are made in all styles and sizes, for pleasure cars, trucks and commercial vehicles and they never break. For full information concerning this spring address Tuthill Spring Co., Chicago, Ill.

No-Leak-O Piston Ring.

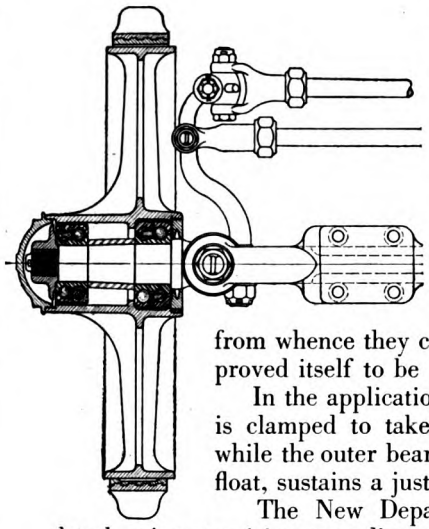
This is described by the manufacturers as a scientific oil packing piston ring. The oil grooves in this ring are kept full of oil, making a perfect fit, also forming a seal, which prevents the escape of gas, and also lubricates the piston ring, thus giving, it is claimed, perfect compression without waste, maximum power with less gasoline, and perfect lubrication without carbon, smoke and oily plugs. Any who may be interested should write for prices and full particulars to the Automobile Accessories Company, 816 West North Ave., Baltimore, Md.

Voltalyte.

This is an acidulated distilled water solution for recharging storage batteries, and the manufacturers state that practical results are being obtained from the use of this preparation. All good reliable manufacturers recommend the use of distilled water for charging batteries, but the acidulated water known as Voltalyte is ideal for the purpose intended. Voltalyte is manufactured by the L. & M. Auto Specialty Co., of 1104 Lexington Ave., New York City, to whom all inquiries should be addressed.

S. O. S. Storage Batteries

These storage batteries are manufactured by the Arsenal Varnish Co., 2501 Fourth Ave., Rock Island, Ill. The manufacturers state that aside from their high voltage maintenance, they will guarantee that S. O. S. battery plates positively will not buckle or sulphate during the life of battery, under any conditions of use or abuse. They can be overheated and overcharged and entirely discharged without injury. Dead short circuits will not harm them. They can stand idle for months without care or attention, and upon being charged will operate to their full rated capacity. They are more nearly fool proof than any other lead plate battery now made. For Varnish Co. and dealers should bear in mind that good selling agents are wanted for this battery in their territory.



Clouse Tire Repair School.

There are many garages and repair shops where a great deal of extra money might by made by adding a tire repair department, and the Clouse Tire Repair School is prepared to teach you every phase of tire repairing and tire construction by practical demonstration, in a school equipped with every necessary appliance. This is not a correspondence course. You get your training by actually using equipment and repair material. All who are interested should send for their free booklet C to Clouse Tire Repair School, Euclid Ave. and 90th St., Cleveland, Ohio.

A Reliable Motor Lock.

A new motor lock is being manufactured by the Atlantic Machine Company, 255 East 15th St., Brooklyn, N. Y. It can be applied to any kind of on engine and it operates with timer ignition. If used on a Ford motor the Elevated Timer Bracket should be included in the outfit. It is easy to apply, simple to operate and is absolutely effective. It is not a complicated or cumbersome device and will not get out of order under any circumstances. The price is low and a car owner may rest assured that when used it makes an engine absolutely inoperative. For full particulars address the manufacturers as above.

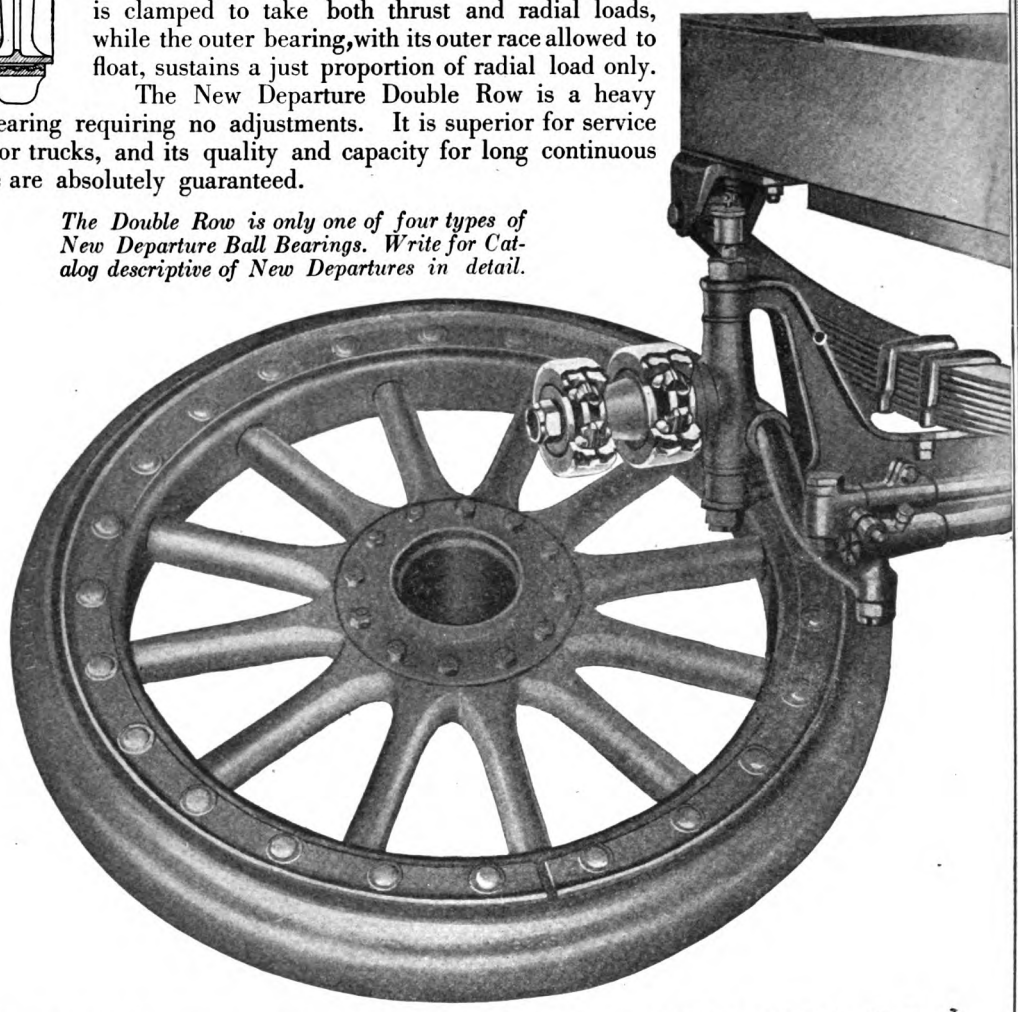
NEW DEPARTURE BALL BEARINGS



American Made for American Trade

BY reason of their ability to successfully withstand the heaviest of load stresses, regardless of the direction from whence they come, the New Departure Double Row Ball Bearing has proved itself to be particularly well adapted for use in heavy truck wheels.

In the application here shown the inner bearing is clamped to take both thrust and radial loads, while the outer bearing, with its outer race allowed to float, sustains a just proportion of radial load only.

The New Departure Double Row is a heavy duty bearing requiring no adjustments. It is superior for service in motor trucks, and its quality and capacity for long continuous service are absolutely guaranteed.

The Double Row is only one of four types of New Departure Ball Bearings. Write for Catalog descriptive of New Departures in detail.

OPPORTUNITY FOR LIVE, RESPONSIBLE INDIVIDUALS OR FIRMS
that handle automobile accessories to make money selling Gasolette. Choice territory open.

Dealers who sell Gasolette sell a highly serviceable product, and incidentally make a lot of money.

Gasolette users buy it as regularly as they buy oil and fuel. When you make a Gasolette customer you keep him.

Gasolette poured into gasoline increases mileage from 40 to 60 per cent. Guaranteed to contain no ingredient injurious to motors. Gives motors greater power, more speed and 100 per cent. flexibility. Prevents pre-ignition, pounding and overheating of engine. Guaranteed to remove and prevent carbon deposits.

Quart can (will treat 64 gal. gasoline), $1.35.

Sent prepaid upon receipt of price.

Write for our unique co-operation sales proposition.

VOLTALYTE

An acid solution for replenishing Electric Storage Batteries in commercial use, on Automobiles, Boats, Railways, etc.

Maintains the proper Specific Gravity of Acid in battery when charged, prevents low voltage, high internal resistance, dim lights and weak discharge for self-starting, gives your dynamo a chance when battery is low, lengthens the life of battery, gives you more reliability and satisfaction and saves repair bills.

QUARTS, HALF GALLONS, CARBOYS.

Branch: 282 Halsey Street, Newark, N. J.

DOUBLE TREAD
YOUR OLD TIRES
Why not reclaim your old worn out or rim cut tires and have from
2,000 to 5,000 MILES MORE USAGE?
Send us two old tires, one with a good bead, the rubber could be all worn off, and the other with a good tread but can be all rim cut or blown out on the side, and we will combine them into a sound one by our
DOUBLE TREAD RECLAIMING SYSTEM
For a cost of from $2.00 to $4.00.
If you have only one tire in this shape we can furnish you with the other one at a cost of from $4.00 to $9.00. If you have no old tires to have remade you can purchase ready remade ones that we carry in stock. All sizes, from $4.00 to $12.00.
ASK FOR OUR PRICE LIST.

"Oh, Yes! I've Seen That Fellow's Advertisements For Years"

Men who buy their cigars from me know that they have the "inside track" in cigar buying. They know they are buying cigars that suit them at about half what they would have to pay at a retail store.

So they pass them out occasionally. And when the cigar is complimented they explain that it "is the Shivers Panatela, made by Shivers, the man in Philadelphia who sells his cigars direct from his factory, you know."

Shivers' Panatelas
EXACT SIZE AND SHAPE

And in nearly every case the other man says: "Why, sure, I know whom you mean," etc.

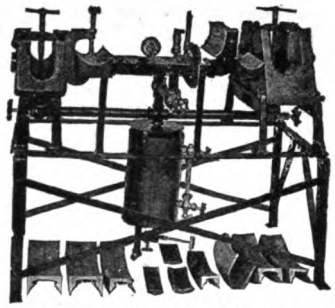
He has seen my advertisements, but somehow he never has ordered my cigars.

I wonder why not. Does he read the advertisements through? Does he read my offer, set in blackface type?

MY OFFER is: I will, upon request, send fifty Shivers' Panatelas, on approval, to a reader of the *Automobile Dealer and Repairer*, express prepaid. He may smoke ten cigars and return the remaining forty at my expense and no charge for the ten smoked if he is not pleased with them; if he is pleased with them and keeps them he agrees to remit the price, $2.50, within ten days.

Are *you* one of the men who have never ordered?

I make my Panatela with Genuine Cuban Grown, Havana Tobacco. The filler is *all* Havana, long leaf. The wrapper is Sumatra. The cigar is rolled by hand by skilled adult male cigarmakers. It has all the bouquet of Havana, all the uniformity and free burning quality of the hand-made cigar because it *is* a hand-made Havana filled cigar.



You can't lose by trying them. You don't pay out a cent for cigars or express charges until you are sure you are pleased and then you pay only for the cigars. I prepay all shipments.

Since I sell by the box and sell direct, my prices are of course very low, as I have said—about half.

The cigars will sell themselves if you give them half a chance.

In ordering, please use business stationery or give reference and state whether you prefer mild, medium or strong cigars.

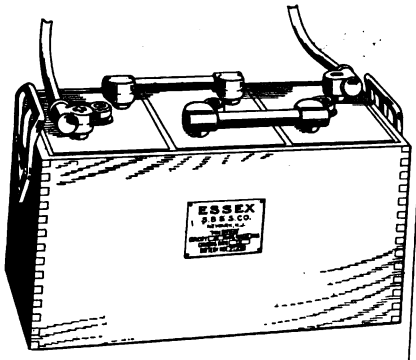
Best in the Long Run

The Perfect Fountain Brush.

This is a brush, especially made for washing automobiles. It can be readily attached to any garden hose, and by its use your car may be effectually washed in fifteen minutes. It is warranted not to scratch or damage the car, and it is also guaranteed to last longer than your car will last. This brush is manufactured by the Howard W. Hicks Brush Company, Denver, Colo., and the No. 2 size, which is the most popular type of this brush, sells for only $4.50, delivered anywhere in the United States. Send your orders and inquiries direct to the manufacturers. If you want a satisfactory washing device, this will probably answer every purpose.



New Era Master Vibrator.

The manufacturers state that this master vibrator is guaranteed for life. Its size is 2x2x5 inches. It is enclosed in a black steel case, weighing only two pounds and fitted with the New Era Indestructible Spark Points. This vibrator is sold under a thirty day trial guarantee of money back if wanted and positively guaranteed for life with no restrictions. The price is $7 by parcel post free, with the dealers' usual discounts. Address all inquiries direct to the manufacturers, New Era Spring and Specialty Company, 872 Woodward Ave., Detroit, Mich.

Storage Battery Replacements

The Essex Storage Battery & Supply Co., Inc., 272 Halsey Street, Newark, N. J., makes a specialty of replacing storage batteries with batteries of their own manufacture of the same type and size as the batteries taken out. This company has made a study of all the different sizes which are brought out by the other manufacturers of batteries and no

matter what the shape or the size of your battery box may be, they can arrange for a prompt replacement. The Essex storage batteries are of the highest quality and guaranteed to give perfect satisfaction. Correspondence is invited from car owners and garage proprietors.

Tire Dealer Comes Into His Own.

Thousands of tire dealers have indorsed the Goodrich "fair list" price plan—to sell tires on a price list which is net, instead of selling by discounts. Consumers everywhere are recognizing the value of the "fair price list" which puts tire buying on a one-price basis—every man knowing he is getting just as low a price as his neighbor. This condition is impossible under the discount plan in which the padded price list has played such a part in the past. The Goodrich "fair list" plan carries with it a substantial price reduction, and the move which has effected the whole tire industry and which means so much to the tire user, still is the chief topic of discussion among automobile and tire men and motorists. This is no price-cutting war involving tire manufacturers. It is an effort on the part of the manufacturers to protect the consumer from concerns which slash prices on a list "marked up" for that very purpose, so that the user is puzzled to know whether he is getting the best or the worst of it. The deliberate reduction of prices and establishment of a "fair price list" that is standard for that specific make of tires, it is believed, will conserve the interests of the motorist and promote better feeling between tire maker and car owner. With Goodrich "Fair-listed" tires he now can be sure of just that—he knows he is paying the fair price—that he is buying a standard, high-grade article that has one price the country over, whether he buys in Maine or California, whether he buys in the city store or the road side shop, in a hurry or not, he always pays one price—a fair one—that protects motorist and dealer alike.

New Era Toricle Goggles.

The manufacturers of these goggles claim that they have many special features of merit and dealers as well as car owners are notified to write for full particulars concerning this line of goggles to the New Era Optical Co., 123 W. Madison St., Chicago, Ill.

Change of Ownership.

The Service Gear & Machine Co. of Reading, Pa., has purchased the entire stock of gears and shafts, patterns and eccentrics of the service department of the American Die & Tool Company of the same city, the well known manufacturers of tranmission and rear axle equipment for automobiles. The Service Gear and Machine Co. will endeavor to maintain a permanent stock of the transmission gears, splice shafts, countershafts, bevel differential gears and axle shafts for the majority of the obsolete cars manufactured in this country. The stock will be carried at Reading and dealers will be appointed throughout the country to act as agents for this concern. The Service Gear and Machine Company will have no connection whatever with the American Die & Tool Co., which will continue its existence as a separate organization.

Ford Valves.

The Michigan Engine Valve Company of Detroit, Mich., manufactures valves of every description and makes a specialty of Ford valves. Their valves are made with carbon or nickel steel stems and cast iron heads, fused by an up-to-date process that fuses the head and stem together the entire length of contact. Every valve is guaranteed as to quality. Valve blanks can be furnished for any size valve for repair work and valves can be furnished to blue prints or samples. Write for prices on finished valves or price list on blanks. Prompt service and reasonable prices are guaranteed, together with a first class product.

The Comfort Safety Steering Device.

This is a special device for Ford cars for relieving the driver of strain and tension of the muscles, and it is claimed that it reduces fatigue to a minimum. It also eliminates the possibility of wheels "doubling up" when driving through the sand, and lessens the friction and vibration of the steering column. It saves the tires by preventing the wabbling of wheels. Dealers find a ready market for this device. The list price is $5.50 and where you cannot obtain the article from your dealer the manufacturers will ship it to you anywhere in the United States on receipt of the price. Address The Comfort Motor Machine Company, Denver, Colo.

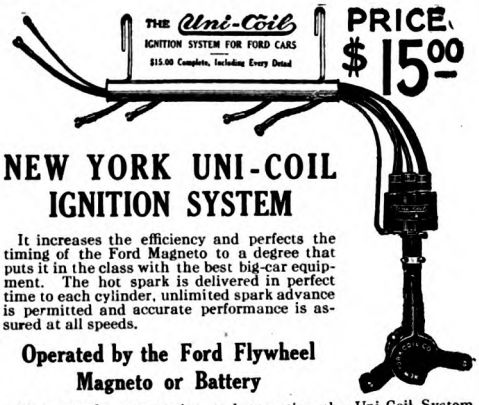
New York Coil Co.

"Easy Selling" FORD Accessories

Six Years of Success on Thousands of Ford Cars is the Record of

THE NEW YORK MASTER VIBRATOR



It blazed the way for better operation through improved ignition. Many times imitated, it has had no rival in efficiency and knows no competition to-day. It has an immediate effect on Ford performance. Thousands of users have found that smoother running, better ignition and easier starting resulted at once from an installation of this master vibrator.

Does Not Stick
Never Gets Out of Order

The "New York" makes the minimum of demand on the time and attention of the user. No other type of master vibrator can run so long with so little adjustment and correction. The hot powerful spark that it produces means clean and complete combustion. This eliminates the prime cause of carbon deposits in the cylinders. A clean motor is economical—there is no waste of fuel and no decarbonizing expense. Special contact points are provided and these are supplied in **sealed red envelopes** bearing our name—the user's protection.

Price Complete, $10.00

NEW YORK UNI-COIL IGNITION SYSTEM

It increases the efficiency and perfects the timing of the Ford Magneto to a degree that puts it in the class with the best big-car equipment. The hot spark is delivered in perfect time to each cylinder, unlimited spark advance is permitted and accurate performance is assured at all speeds.

Operated by the Ford Flywheel Magneto or Battery

With simple construction and operation the Uni-Coil System embodies all the vital factors in magneto efficiency—for example: a magneto contact breaker with only one pair of adjustable contacts. Another feature is an advanced type of high tension distributor, using but one of the standard Ford coil units. A complete installation is readily effected and the result is to simplify the Ford ignition apparatus, eliminating the complex wiring and timers and substituting a system that every Ford owner can understand.

Price $15.00 Complete

The Highest Priced Cars are No More Comfortable than the Ford if our Shock Absorbers are fitted

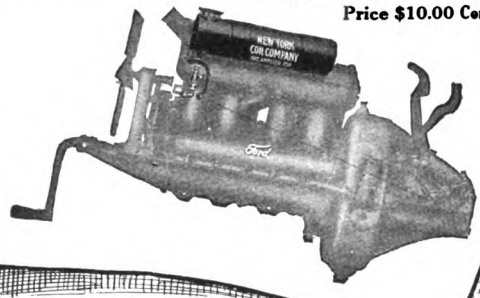
It is quite possible to secure the most luxurious riding qualities in a Ford car—when you show the Ford owner how to do this at a minimum of cost, he will spend his money with you. It will cost him just seven dollars and fifteen minutes' work installing the

NEW YORK SHOCK ABSORBER

on his car. He won't have to remove wheels, radius rods or spring perches—nothing is touched but the shackles. A set of four ($7.00) can be installed without difficulty and the car driven away twenty minutes after the first move is made. The result will be noticeable at the first bump, but the bump won't be. This is due to the **all-around** shock absorbing efficiency of the "New York." It operates in two directions and eliminates side-sway as well as jolt and vibration.

Price $7.00 Set of Four

Our Selling Terms Insure You a Liberal Margin of Profit



Perfect Lubrication Conserves Mechanical Efficiency

Hap-hazard lubrication is poor economy. Too much or too little oil costs more than just enough. Excess means stickiness and gumming with heavy carbonization—shortage of oil means friction leading to rapid depreciation of moving parts. The solution of the problem lies in the installation of the

NEW YORK Constant Level Lubricator

A scientific lubricating controller that works in accurate unison with the motor. **Oiling starts or stops with the starting or stopping of the car. A constant level** is maintained in the crank case. Fresh unused oil is supplied at the demand of the motor. The device is of simple construction and unfailing efficiency. No gears, belts, cams, rods, air pressure or other dubious resorts are used. There is nothing complex to cause trouble. Technical details on request.

Installed in 15 minutes

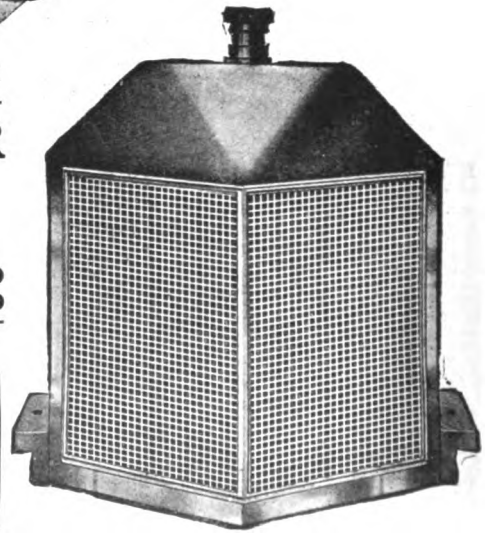
WRITE US AT ONCE!

MAKES THE FORD A CAR OF BEAUTY

This is a Ford Specialty which any dealer can sell in great quantities for it so transforms the Ford that it looks like a $2000 car. Any Ford owner will be glad to change his homely hood for this Stream-Line bonnet whose tapered up-to-date lines add so much distinction to the appearance of his car, at such Little Cost.

PAT. APPLIED FOR



The "Superior" Stream-Line Hood is made of heavy gauge pressed steel, and has 7 ventilator gills on each side; is built solidly and substantially and will not rattle or creak. There are no exposed hinges on top, preventing rain or water from getting on the motor or wiring—and comes ready to attach. A special hood rest is included.

DISCARD the SLEDGE and Save Money with the WEAVER GARAGE PRESS

20-TON CAPACITY

YOU can't afford to spend two or three hours on a job which *should* require only that many minutes. Neither can you afford to turn out a job which is crudely and unsatisfactorily executed simply because you haven't the equipment to do it as it should be done.

This Press Will Soon Pay For Itself

—in the time and labor it will save on the many different jobs you are daily attempting to handle with improvised methods,

—in the revenue on work which other shops will bring to you as a result of your installing this equipment,

—in the cost of the material and parts which you are now compelled to replace on account of their being ruined as a result of improper handling,

—in the additional patronage you will receive from the motor public as a result of your being equipped to give more prompt, efficient and satisfactory service.

Designed for Garage Service

This Press is built to accommodate all classes of garage work. Note that it has sufficient width to permit it to receive the largest wheel for pressing hubs, bearings, etc., in or out. (*See cut.*)

CRANK SHAFTS and similar BULKY pieces may also be readily handled by reason of the divided bolster as shown herewith.

Wonderful Leverage

The lever construction supplies a leverage of 1,500 to 1 so that the maximum pressure of 20 tons can be developed by one man with ease.

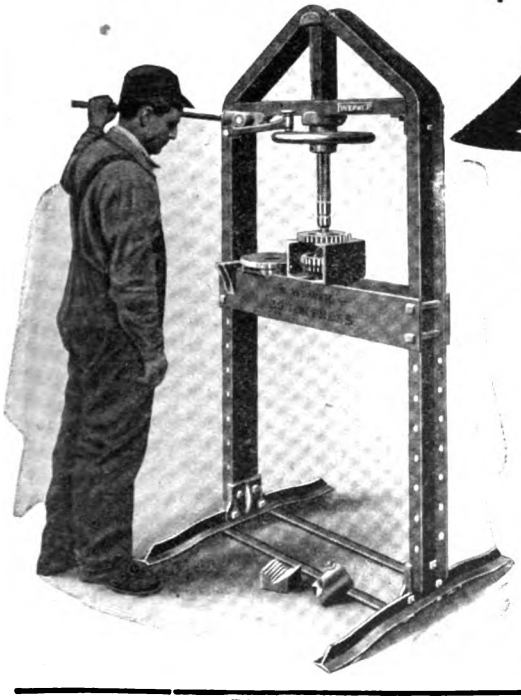
Vice Block Attachment

We furnish a vice block attachment as part of the regular equipment which operates beneath the screw and provides a means of holding work against a severe twisting strain.

CONSTRUCTION The frame is of one piece of heavy channel steel; the hand wheel is 15 inches in diameter, and the weight of wheel and screw is carried upon ball bearings. The hand lever has a leverage of over 1,500 to 1. The thrust of the screw is directed against heavy Bronze Thrust bearings. The screw is 2 inches in diameter, with 3-pitch Acme thread, and has a range of movement of 12 inches. ***The screw does not revolve.***

The bolster which carries the plate can be set at any desired height with extreme adjustment of 48 inches. The width between frame uprights is 32 inches. Floor space, 36x36 inches. Weight, 425 pounds.

NET PRICE, Complete with Equipment, **$48.00**



WHICH METHOD would YOU prefer FOR THESE JOBS ?

- Forcing Transmission Gears
- Forcing Fly-wheels from Crank Shafts
- Straightening Frames
- Pressing Piston Rings in or out
- Forcing Hubs in Wheels
- Pressing Bushings on Connecting Rods
- Forcing Starter and Generator Gears
- Straightening Axles
- Pressing Ball Bearings in Wheels
- Forcing Drive Shaft Gears
- Straightening Shafts
- Forcing Ball Bearings from Crank Shafts
- Straightening Rear Systems

WITH VICE BLOCK

- Holding Differential Housings and Other Awkward Work
- Holding Pipes and Rods for Cutting Threads
- Holding Axles and Shafts Against Twisting Strain

THE SAVING on a very few of these operations **WILL OFFSET THE ORIGINAL COST of the PRESS.**

WEAVER AUTO TWIN-JACKS

A POSITIVE GUARANTY

THE STRONGEST EVER MADE

Guaranty

Every part of the Hoosier Tandem guaranteed absolutely for one year. This includes the contact points. Any necessary replacements will be made, free of charge, at the factory, the user paying simply the transportation charges.

HOOSIER TANDEM MASTER VIBRATOR

Dealers and Jobbers can now assure their customers of continuous satisfaction.

The Only Vibrator Which Cannot Stall The Car By Sticking.

The Hoosier Tandem has TWO PAIRS OF CONTACT POINTS—instead of one, as have all other vibrators.

Sticking points have always been the cause of vibrator troubles—of vibrator-equipped Ford cars stalling.

The heat produced by the sparking of the points is what makes single-point vibrators stick.

It's the tandem points that make the Hoosier different.

No other vibrator has them.

The kick switch has a removable key, preventing tampering with the car.

The case is solid mahogany, highly polished, 7 inches high, 4 inches wide and 3 inches deep.

The Hoosier Tandem points cannot heat to the sticking point—because they alternate the work of sparking. Neither operates long enough at a time to make sticking possible. The two sets of points are constantly automatically relieving each other under service.

Write us now, today, about your 1915 vibrator requirements. We have a proposition that means more vibrator sales and bigger profits to jobber, dealer and garageman.

If you dealer does not carry the Hoosier Tandem in stock, MR. FORD OWNER, order one direct from the factory. We guarantee it to you on a "money back" basis.

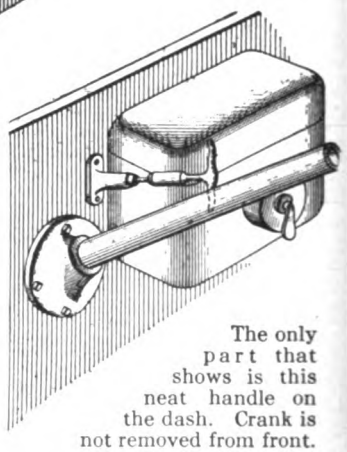
$10

Think of it!

A SELF STARTER FOR 10 DOLLARS

The HUNTER

Complete with all attachments and instructions



JUST WHAT THE FORD OWNER HAS BEEN LOOKING FOR

At Last Mr. Ford Owner!

Your wish has come true. The best starter for a Ford car ever devised and costs less money. It gives you every convenience of the bigger, costlier cars (as you can use electric headlights on your magneto current).

INSTALLED IN ONE HOUR BY ANYONE

The only part that shows is this neat handle on the dash. Crank is not removed from front.

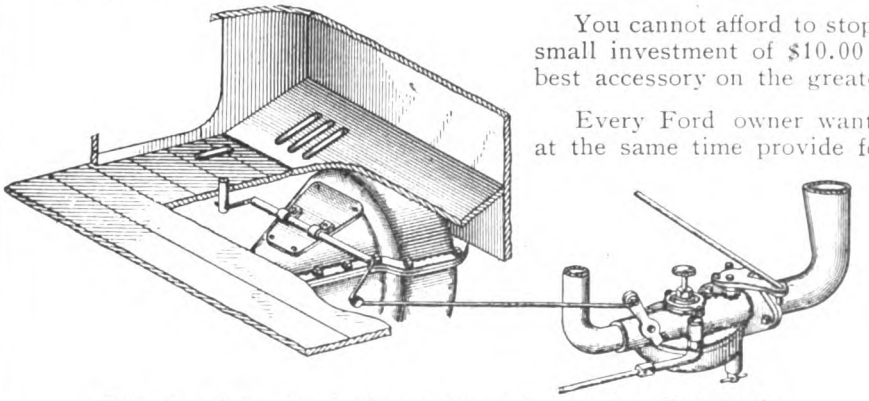
INCREASES THE VALUE OF A FORD THREE TIMES

Note the Advantages

Powerful—The straight pull and powerful leverage enable a woman or girl to start it.

Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.



Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.

You cannot afford to stop at the small investment of $10.00 for the best accessory on the greatest automobile on the market.

Every Ford owner wants to make his car up-to-date and at the same time provide for comfort.

This view shows the simple attachment for shutting off air intake of carburetor to insure easy starting in winter weather.

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. Big money for you in this—the lowest priced reliable Ford Starter made.

HUNTER LOCKS for FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. Price, $1.00. Quickly installed. Sold by leading dealers.

Compare These Two Batteries

Both are 6 volt 80 ampere hour lighting batteries. They are an eloquent object lesson. The smaller battery purchased from a Chicago jobber, August 27th, 1914, contains only five plates per cell yet is rated as a 6 volt 80 ampere hour battery.

The S. O. S. battery illustrated is rated as a 6 volt 80 ampere hour battery and contains thirteen plates per cell. By a jobber the S. O. S. would be rated as a 6 volt 120 ampere hour battery. S. O. S. batteries are conservatively rated, while most jobbers' batteries are much overrated to enable them to make a close price. An S. O. S. battery means full rated capacity and SATISFACTION.

Owing to a slight change in sizes of S. O. S. 6 volt 80 ampere hour lighting batteries, we have 150 of them, the following outside dimensions, that we are selling while they last at $20 each. Length 11 inches, width 7½ inches, height 9 inches. Shipping weight boxed 65 lbs. These are the same as battery illustrated. If you want the best lighting battery made, order today.

Paint Your Own Car

SAVE $25 to $50

Our big, 36-page book, "THE CAR BEAUTIFUL," is the recognized authority on the Home Painting of Motor Cars. After reading it, you yourself, without previous painting experience, can successfully repaint your car or only revarnish it, or enamal the hood and fenders, enamel or silverplate the lamps, etc., redress the top and cushions, paint the wheels a different color—in fact, do anything you otherwise would have to pay a professional painter big money to do.

During the past eight years, thousands of motorists have successfully painted their own cars with our materials. The Arsenal System of repainting Motor Cars (for novices) is one of the big successes of the industry. DON'T SPEND A CENT FOR PAINTING MATERIALS UNTIL YOU HAVE READ THIS BOOK. Send for your copy today. It is FREE.

Replace Your Broken Curtain Light Yourself

THE REPLACE CURTAIN LIGHT is a complete unit and can be installed by anyone without experience. No sewing is necessary, and no tools required. Each light is complete with fasteners for applying. Curtain lights break easily and must be replaced from time to time. If no carriage trimmer is available and a light is to be replaced, the curtain must be taken off and shipped to some repair shop or factory. Heretofore the celluloid lights have of necessity been sewed in the curtain until the REPLACE CURTAIN LIGHT was invented. Now it is only necessary to order the lights from us and you can put them in yourself without taking off the curtains.

Back Curtain Lights for 1912, '13 or '14 Ford touring cars, prepaid, each, $1.50.

Overland touring cars, 1913-14, each $2.50. Others in proportion.

Order a light today and put it in yourself.

NOTE—Patents are pending on the Replace Curtain Light and infringements will be vigorously prosecuted. REPLACE CURTAIN LIGHTS are fully described in our booklet "The Car Beautiful." It is FREE. Send for your copy today.

S.O.S

Trade Mark Registered

Storage Batteries

No other starting battery now on the market can give the satisfactory service and long life that the S. O. S. battery will give—bar none

Aside from their high voltage maintenance, we guarantee that S. O. S. battery plates **positively will not buckle or sulphate during** the life of battery, under any conditions of use or abuse. They can be **overheated** and **overcharged** and **entirely discharged without injury.**

Dead short circuits will not harm them.

They can stand idle for months without care or attention, and upon being charged will operate to their full rated capacity. They will deliver full rated capacity during their entire life.

They are more nearly fool proof than any other lead plate battery now made.

Any S. O. S. dealer will be glad to make a dead short circuit test for you. Ask him to burn up a 20 penny nail by holding across terminals. Or he will weld a pair of steel files together for you in the same manner. This short circuiting causes plates to buckle. S. O. S. batteries can be entirely discharged in this manner without buckling of plates. BEFORE YOU BUY ANY BATTERY INSIST ON THIS TEST.

CAR OWNERS: The S. O. S. costs no more than any high grade battery. It is positive insurance against battery trouble. Send for our free battery book.

S. O. S. Storage Batteries for Starting, Lighting, Ignition, House Lighting, Railway Signal Service, etc. Catalog on Request.

FOR OUR MUTUAL BENEFIT

we ask your consideration of a few facts regarding our product. Facts, which you will readily recognize and grant, but may have previously overlooked.

Who originated a Triple Socket Wrench for Ford Car use? **WALDEN-WORCESTER.**
Who designed the popular short Valve Grinder? **WALDEN-WORCESTER.**
Who applied their time and spent their money in perfecting a Service Set of Tools for Ford Cars? **WALDEN-WORCESTER.**

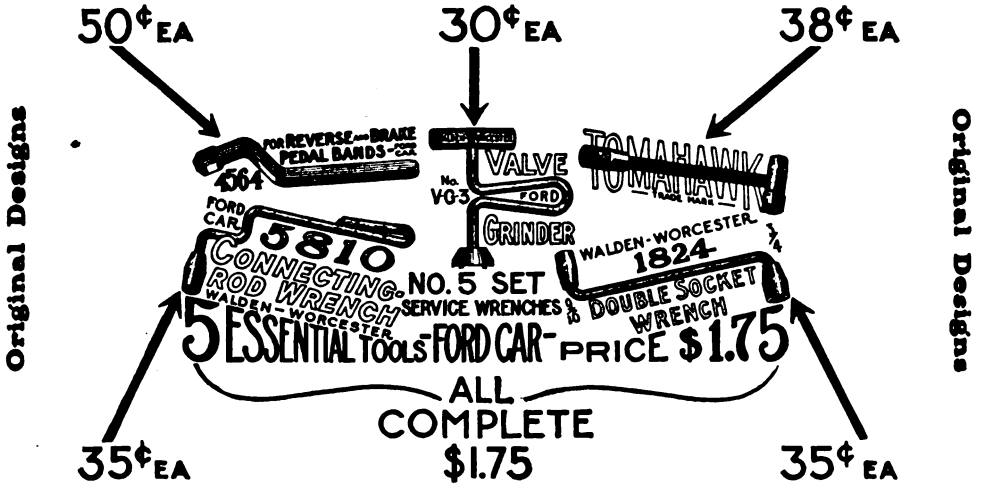
Now, the Point—the Big Idea—Are you selling these **Walden-Worcester** Tools, or cheap imitations?

Are you selling wrenches **built to use,** or others merely "made to sell"?

In other words, are you using our goods, to not only make a profit for yourselves but to build up a permanent business, with patrons who will stick to you because of the quality of your merchandise, or, have you been deceived by the lure of a little more profit into selling "something just as good" and driving away the good-will of your patrons?

Some imitation tools have come to our notice which will not even fit the nut, for which we make a special socket. Do you not agree with us that such goods would drive away your trade?

You are in business to build up a permanent clientele and we ask your co-operation so that our tools may be a source of pride and profit to you in selling them, and of satisfaction to your patrons in using the **best made.**



ALL ORIGINAL DESIGNS

WALDEN - WORCESTER GUARANTEED QUALITY TOOLS

The first wrench ever offered for use on brake and reverse bands, designed with a knowledge of clearance around the nuts. The peculiar shape of the handle is to allow for full working space.

New design, all steel tool. Bar handle swivels on cone bearing. Pins are hardened steel and socket shaped to fit valve head—a real tool.

Most useful single wrench for Ford Cars. Cylinder Head Bolts, rear axle nuts and housing, water intake pipes and sundry other places. Sockets are shaped to allow full clearance.

It will fit any rod in practically any position without removing the engine from the car. The first and only wrench on the market today which will accomplish this purpose.

There are many nuts and bolts on the Ford Car which with ordinary wrenches are very inaccessible, causing much loss of time when making adjustments or repairs. These tools are designed and tested under practical service conditions and greatly simplify the work, saving much time and annoyance. The tools are built to meet hardest service conditions and are fully guaranteed. Every Ford owner and garage needs these tools.

Sizes are ⅞ and ¾ in., to fit main bearings and engine base bolts and other parts. Most desirable tool for your Ford equipment.

DESIGNED AND PROVEN FOR EFFICIENCY AND SERVICE.

A NEW BIG VALUE IN SERVICE WRENCHES FOR FORD CAR

If your dealer or jobber does not carry these tools, advise name and we will ship, charges prepaid, on receipt of price.

Send for Catalog and Trade Prices. **Walden Mfg. Co., 64 Central St., Worcester, Mass.** **We Manufacture Wrenches Only.**

10,000 MILES GUARANTEE BACKS THIS TIRE

Brictson Pneumatic Tires

TRY Brictson Pneumatic Tires at our expense. Don't pay until you are satisfied. At our risk find out for yourself what wonderful service Brictson Tires give—how resilient and easy riding they are. Get rid of punctures, blowouts and rim cuts. Brictson Tires are rut proof, oil proof and gasoline proof. They are sold under a specific 10,000 mile written service guarantee.

Read What One User Says

"Several months before beginning my trip from Detroit, Mich., to Detroit, Fla., I thoroughly investigated tires of several well advertised kinds. I finally decided for my trip that the Brictson was the most economical and durable tire that I could find.

I am daily asked if I have many punctures. I reply that I do not know what a puncture is. I am driving on all kinds of roads under all kinds of conditions and never have a thing to worry about.

I have been on the road since the 8th day of last October, and if all goes well will begin my Florida trip again about October 1st next. I consider the tires worth almost their weight in gold. I would not do without them at twice the price.

W. J. BREWSTER,
August 10, 1914. 236 Jefferson Avenue, Detroit, Mich."

Your Tires Rebuilt the Brictson Way

If the fabric in the tires you are now using is in good condition, we can take them, make them proof against rim-cutting, punctures, blowouts, side-wall breaks, skidding, ruts, oil, and give thousands of miles of additional service.

Sign and send back coupon for full information and details of our liberal Free Trial Plan.

WHAT DO YOU DO WITH A TIRE LIKE THIS?

The fabric foundation of the tire is uninjured though the rubber tread is worn and torn away. If continued in service in its present condition with the fabric exposed to water-soaking and wear, the best that can be expected is a few hundred miles of service at the most.

If this tire is fitted with a new wearing surface that will keep water away from the fabric and take up the wear, it can reasonably be expected to give just as much mileage as if you bought a new tire, and best of all, the cost of having this tire rebuilt is but a fraction of the cost of a new tire.

Diamond, Goodrich, Fisk, Firestone, Goodyear, Miller and United States Tire Companies will all confirm this statement.

RETREAD IT BY THE TRIPLE TREAD PROCESS

The Triple Tread process of retreading has six marked points of superiority over any other retread process now on the market:—

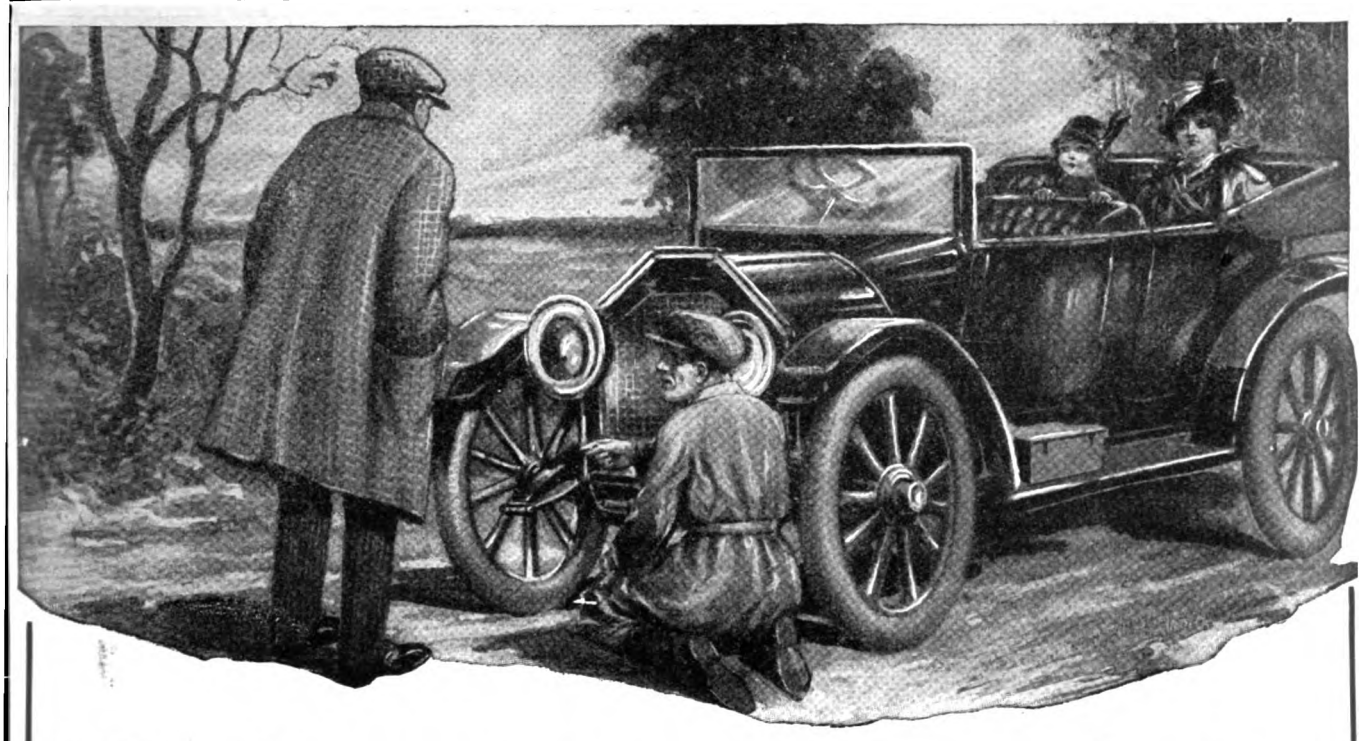
1. A tire retreaded by the Triple Tread process is made absolutely non-skid.
2. A tire retreaded by the Triple Tread process is made practically puncture proof.
3. The Triple Tread process of retreading is the only one in which there is no possibility of over-curing the fabric foundation of the tire.
4. The Triple Tread process is the only retread process which will add strength to the fabric foundation of the tire so retreaded.
5. The Triple Tread gives better protection against glass cuts, stone-bruises, etc., than even a new rubber tire.
6. The Triple Tread is the only retread that is not absolutely dependent on the life of the fabric of the tire retreaded for its full mileage.

3,500 MILES GUARANTEED

The Triple Tread is guaranteed on the same basis as new tires, 3,500 miles, and is guaranteed perfect in material and workmanship.

Inside linings may reinforce the fabric from the inside but will not protect that fabric from wear or water-soaking after the rubber tread is injured.

Tire protectors will give protection against punctures and glass cuts but are unsightly, heavy, and cause friction between tire and tread which is injurious to both tire and inner tube.



The Triple Tread process of retreading has a distinct individuality and is enabling hundreds of motorists to get thousands of extra miles out of tires that they formerly discarded as worthless.

Write for full particulars and prices today. Please mention the size of your tires.

SIT STIL!

START YOUR ENGINE FROM THE SEAT WITH A SIT STIL CRANKER

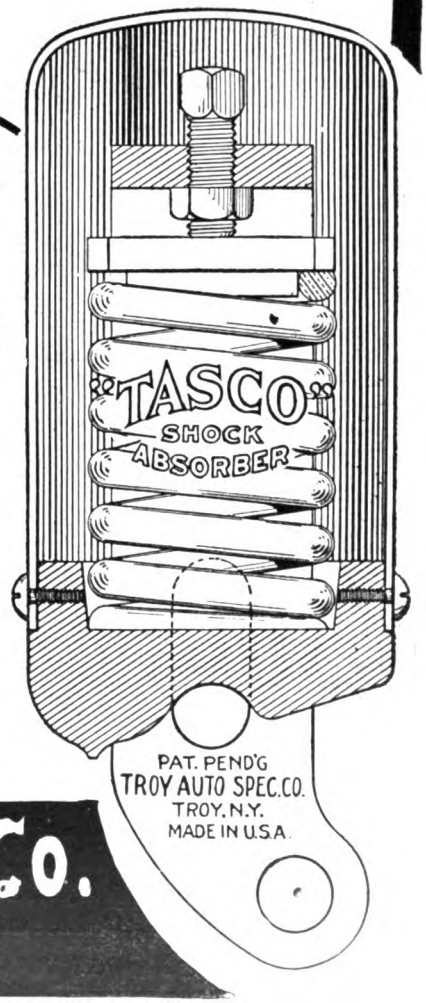
There is no need of getting out in the muddy gutter or dusty road to crank the motor. You can start it from the seat every time, without danger of getting hurt, and without as much effort as in cranking.

The Sitstil turns the Ford motor over five times as fast as you can crank it by hand. That means easy starting because the speed of the motor draws in a good charge of well vaporized gas, and the magneto generates a good fat spark to ignite it. Operated by a foot pedal—the easiest way. A woman can do it. It is more positive than the expensive electric starting systems.

$15. Ten Days' Trial—Money Refunded

We will cheerfully refund your money if you want it after you have tried the Sitstil on your Ford. Price includes seat Primer attachment. Easily installed. Simple, handsome, well-made best materials.

"TASCO" SHOCK ABSORBERS FOR FORD CARS



Built of Steel—Designed for Service.

$6.00 FULL SET OF FOUR

The day of high priced Ford Shock Absorbers is past. No Ford owner will pay more than $6.00 a set for them when he knows that the "Tasco" Shock Absorbers are not excelled by any in efficiency, strength and easy riding.

"Tasco" Shock Absorbers do not raise the car or change the suspension as designed by Ford engineers. Made of finest material, properly designed and have real springs—strong, lively and flexible. Springs are adjustable. Easily attached without even taking off wheels.

Ten Days' Trial—Money Refunded

DEALERS: We have a good proposition to make you. The "Sitstil" Cranker and "Tasco" Shock Absorbers are the best sellers of their kind on the market.

You can sell this new Gould Starting and Lighting Battery without half trying

Many of the earlier lighting and starting batteries are giving trouble and will soon have to be replaced.

This means good business to dealers and repairmen who arrange to sell the Gould hard-paste-plate high-capacity long life battery—which offers good profits and makes pleased customers every time.

As the point by point comparison shows, our improved 1915 type is the biggest advance ever made in lighting and starting battery construction.

This battery is solid as a rock, gives a wealth of power and will easily outlast the car in which it is installed. We furnish every desirable size.

Sixteen years of progressive development has made the Gould product a leader and has necessitated a plant employing over 4000 men.

Selling Gould Starting and Lighting Batteries for gas cars and Gould renewal plates which fit the jars of any electrically driven vehicles, is sure to develop into good business, especially that our policy is to aid local garages and charging stations in every possible way.

Mail the coupon and get our prices so that you will be in position to act the next time you need a battery.

A NEW FORD CAR

EQUIPPED WITH A

PEDERSEN LUBRICATOR

WAS RUN OVER 6000 MILES WITHOUT REGULATION.
Fill the Oil Tank and the Lubricator Does the Rest.

FOR FORD CARS

$7.50

This lubricator is positive, entirely mechanical in its working and not depending on gravity and pressure. It has no belts, cams or rods to become deranged, but is attached direct to the engine, *starting and stopping with the motor.*

It insures proper lubrication of the motor, with longer life, smoother running, more power and fewer repair bills. It has a half-gallon oil tank, and allows the car to be driven for hundreds of miles with one filling of the tank.

Applied to the car by anyone in 15 minutes.

THE "UNITED TERMINALS"

as illustrated in above cut are the greatest convenience and trouble saver for Ford users. They bring all the wires on top, easy to get at, preventing them from getting oil soaked, twisted or strained at their connections. Should be on every Ford car.

Easily Applied ***Price 50c.***

Dealers write us, you can make money in handling these goods.

Don't You Care, Dad, Tire-Doh Will Fix It in a Jiffy!

No matter how big the puncture, blow-out, or tear, you can repair it yourself in a jiffy with

TIRE-DOH

TIRE-DOH is the handiest repair made for tube and casing troubles. You can use it anywhere—in the garage or on the road—without heat—without tools—and the cost of repairing the average puncture with TIRE-DOH is only 2 cents.

Tire-Doh Repairs are Permanent Repairs

TIRE-DOH is not only easy to use but it makes repairs that will last as long as the tube itself, because it is made of the highest grade rubber. After setting (which it does in a few minutes), TIRE-DOH becomes as tough and elastic as the best inner tube made.

On account of its plasticity, TIRE-DOH can be worked into repairs that are inaccessible to other repair methods.

TIRE-DOH is wonderful for filling cuts and sand blisters in casings too.

Six years on the market and the fact that more than 250,000 car owners use TIRE-DOH and thousands of dealers sell it, is your best guarantee that it does the work.

TIRE-DOH also repairs other rubber articles—rubber boots, gloves, hot water bags.

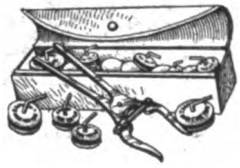
It PLUGS The Hole and It HUGS The Hole

Sampson Puncture Plug

For Automobile Inner Tubes—Quickly and Permanently Repairs the Puncture. Cuts down the cost of repair to a minimum. No cumbersome tools or heating irons necessary—only one small tool and your bare hands.

This cross section view of the working of the SAMPSON REPAIR PLUG shows how thoroughly the tube may be repaired in a few seconds and the way the edge of the plug presses against the shoe, LEAVING NO LUMP.

The strong metallic disks are covered with rubber of the finest quality. The rubber jacket extends beyond the edge of each disk, as here shown.



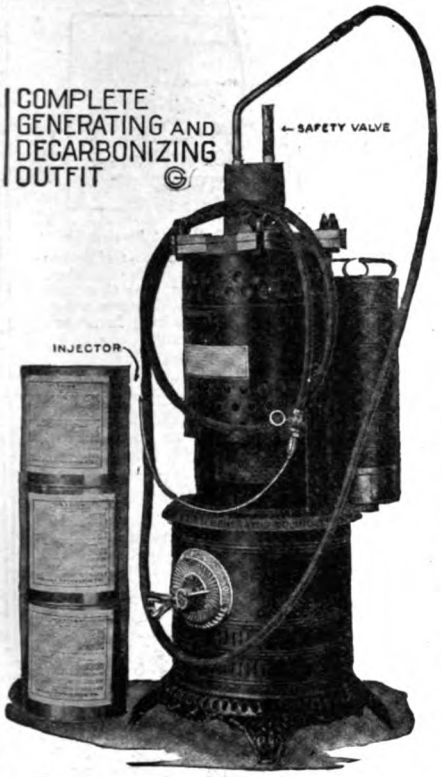
When the two disks are brought together by a wire thumb-screw, which is then broken off, the pressure of rubber against rubber—of the two halves of the plug against the rubber of the tube—makes a complete and permanent repair. This method of drawing the two sections of the plug together making a tight joint with the tube is good tire practice, and universally used by every manufacturer to fasten the valve stem to the inner tube. Good for 30,000 miles if the tube itself holds out.

Positively cannot leak, chafe or wear—will outlast the tube.

No Cement No Cleaning No Waiting

A two-minute repair as permanent as vulcanizing.

Booklet Mailed Free on Application



Dealers, Stock up for the season's demands

PRICES:—No. 1 Sampson Repair Kit, Containing 1 Tool and 1 Doz. Assorted Plugs, $2.50. No. 2 Sampson Carton Kit, Containing 2 Tools and ½ Doz. Assorted Plugs, $1.50.

REPAIRING TIRES

The biggest money making field in the Automobile Industry today is in **repairing tires.** It is an enormous field and growing larger every year. Locations for good tire repair shops are open in every city and town in the country. You can make

$1500 TO $5000 A YEAR

if you learn by our system of instruction. We teach you every phase of **TIRE REPAIRING and TIRE CONSTRUCTION** by practical demonstration, in a school equipped with every necessary appliance. This is not a correspondence course. You get your training by actually using equipment and repair material. That's the only way.

WE TEACH YOU BUSINESS METHODS

Instruct you how to open your shop. How to take care of sales. How to retain your trade. How to make your shop pay.

WHAT OUR STUDENTS SAY

O. E. Bonnell writes, "I did a $15,000 business last season." **A. A. Robinson,** "Have been in business 30 days. More than doubling expenses. Did not know money could be made so easily." **C. E. Kurtz** says, "We are crowded with work." **C. M. Marsh,** "Business coming too strong, and I have not advertised a bit." Hundreds of others tell of similar successes.

SEND FOR OUR FREE BOOKLET C

It tells all about our school, about our methods of teaching, what our students have accomplished. Be first to enter into this big paying business in your town.

CLOUSE TIRE REPAIR SCHOOL

Euclid Avenue and 90th Street, CLEVELAND, OHIO

90% of motor ills are traceable to faulty lubrication. Often an inferior lubricant is directly responsible---a lubricant with an asphaltum base.

HARRIS OILS and GREASES, made of finest Pennsylvania Crude, have a paraffin base. Paraffin is a lubricant—asphaltum is not. Asphaltum means carbon deposit. There is not a trace of it in HARRIS products.

The wiser, more progressive dealers are handling HARRIS OILS and GREASES. Their customers who have tried these pure oils accept no others. Remember,

"A Little Goes a Long Way and Every Drop Counts."

RADIATOR MEDICINE

REPAIRS LEAKING RADIATORS AND WATERJACKETS IN 10 MINUTES

When you pour "X" in the radiator it goes straight for the leaks and seals them absolutely by the action of the cold air. An "X" repair will stand 100 pounds pressure in a steam boiler. "X" is used by large concerns in heavy delivery trucks. "X" will work in alcohol. The most wonderful property of "X" is the fact that it

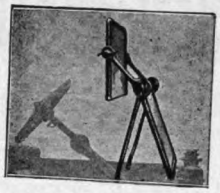
MAKES NEW OR OLD RADIATORS LEAK-PROOF

Because "X" stops automatically leaks due to wear and prevents leaks due to pitting and rust. "X" eliminates scale.

WOULD YOU SWALLOW CEMENT?

If you swallowed cement it would clog your system. Cement and powder radiator compounds will clog your radiator. Use "X" because it is **liquid and cannot clog** the finest honeycomb radiator.

PRICE $1.50 PER CAN



Enough to repair two 5 gallon radiators.

Dealers—Write for Liberal Discounts.

MORE POWER
AND A CLEANER MOTOR

Increases Mileage Per Gallon From 40 to 60 Per Cent
Decreases Fuel Cost of Operation In Like Percentage

A money saver for the user.
A money maker for the dealer.

Those who use it come back for more, and so, you Mr. Dealer, can have a steady income from its sale, if you will take up the proposition we have to offer you.

Write for FREE territory selling plans, etc. Also ask for testimonials, letters, or better still order a quart can "GASOLETTE" prepaid (it will treat 64 gallons Gasoline) and convince yourself of its wonderful merits.

Quart Can (will treat 64 gallons Gasoline).....$1.35
Gallon Can (will treat 256 gallons Gasoline)..... 5.00
Never Sold In Bulk

UNITED PRODUCTS MFG. CO.
219 EAST 22nd STREET Dept. A CHICAGO, ILL.

GASOLETTE

Increases the efficiency of Gasoline without injury to motors.

Gives the motor greater pulling power, more speed and 100 per cent flexibility. sparks quicker and helps the engine to almost instantly pick up and to run smoother.

Prevents pre-ignition, pounding and over-heating of engine.

Removes and prevents carbon deposits on spark plugs, pistons, cylinders and valves, and thereby eliminates engine troubles.

Prevents carbon deposits on exhaust valves and seats, thus eliminating cutting and pitting, and consequent loss of power that can be remedied only by grinding valves.

Prevents carbon deposits on intake valves and seats, which deposits cause loss of compression, loss of power and back firing in intake pipe.

Prevents carbon deposits on pistons, gumming and sticking of piston rings, loss of compression, loss of power—and you avoid the trouble and expense of taking down the engine to clean.

Lessens smoke, odor and noise.

Leaves cylinder and valves in an oily condition and therefore adds life to the engine.

TIRES NEED AIR

Not too much, nor too little—but just enough to keep the tire inflated to the prescribed pressure. There is only one safe, sure way to do this and that is to use a reliable, accurate tire pressure gauge and test the air pressure in your tires frequently. Under-inflation with its rim cutting loosening of treads, etc., will never bother you if the pressure is tested by the

ALLEN TYROMETER

TIRE PRESSURE GAUGE

This gauge may be used with the valve in any position, and it is guaranteed absolutely accurate. Made of heavily nickeled, specially drawn brass tubing, with sliding band which holds the indication as long as you want it. Only 4½ inches long with clip attached for carrying in the pocket.

INVINCIBLE INNER TIRES

Make Tires Wear Better

Unless **Invincibles** are used, 9 out of every 10 tires blow out when half worn out.

Half the wear of the tire is lost.

Invincibles save your this extra wear, because a tire equipped with an **Invincible** cannot blow out until worn out.

This saving amounts to over
40% Expense Stopped!

Invincibles are a pliable wall of strength on the **inside** of your tire. No change in tires or tubes needed to use them.

Efficient business men use them in every tire because **it pays.**

General Fire Extinguisher Co. writes:
"We are getting good results from **Invincibles.** We certainly feel they are a good proposition for anyone using pneumatic tires."

Write for their letter in full, new 1915 prices, and other proofs.

Learn why **Invincibles** are superior to all other interliners. Address

ENGINE PRICES DOWN ANOTHER NOTCH!

Look at these Prices!

2 H-P, $34.95; 4 H-P, $69.75; 6 H-P, $97.75; 8 H-P, $139.65; 12 H-P, $219.90.
Other sizes up to 22 H-P, proportionally low.

Direct from Factory to User!

Why pay two prices for any good engine, or take chances on a poor, or an unknown engine, when the "WITTE" costs so little, and saves you all the risk.

WITTE ENGINES, Kerosene, Gasoline & Gas

LET ME send you a "WITTE" engine to earn its own cost while you pay for it. It's cheaper than doing without one. I have proved that to thousands who are now WITTE users.
Ed. H. Witte.

Stationary, Portable and Saw-rig Styles

Liberal 5-Year Guaranty

CASH OR EASY TERMS.

GET your engine from an engine specialist. All my life I have done nothing but make engines. **The success of my customers and nothing else, makes my success.** I've simply got to sell better engines. I can't lose money on an engine and make back the loss on something else. My factory is the only one, that started in the engine business 27 years ago, which has come through successfully under the same management with which it started. Only WITTE engine-quality has made that possible.

It is cheaper and easier to own a "WITTE" engine than to do without one. My New Offer makes it easier to get the work done by machinery than by muscle or brute power. No need now to get along without a "WITTE."

New Book Free My New Book—the finest in the whole engine business—explains all. It tells you how to be sure in your selection, even if you don't pick a "WITTE." Send me your address today, so I can send you this book FREE with my New Offer.

HOW TO JUDGE AN ENGINE
READ THIS BOOK BEFORE YOU BUY ANY ENGINE IT IS SENT FREE FOR THE ASKING.

Important to FORD Owners

The BOSTON STARTER

Is a Time-Tried, Demonstrated Success

The BOSTON STARTER is guaranteed to turn the motor over as certainly as the crank, while the operator is comfortably seated in the car.

The BOSTON STARTER gives the Model "T" FORD CAR the same self-started appearance enjoyed by electrically started cars, at a fraction of the electric starting cost. No batteries, no wiring to require the service of an electrician.

Ford owners – drive right up and ask your dealer or garage man. If he does not happen to know, write our distributor nearest you.

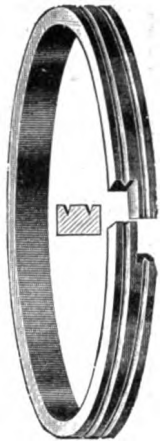
"NO-LEAK-O"

A Scientific Oil Packing Piston Ring

A RING WITH A REASON



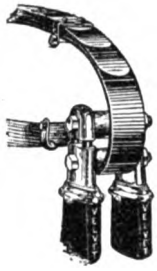
There's no mystery about "NO-LEAK-O" rings. A simple, plain, mechanical fact.

Piston movement, uneven expansion and contraction, makes perfect fitting impossible. It's the OIL that forms the seal, prevents escape of gas and lubricates.

It is only a question of how to keep a volume of oil between the rings and cylinder-wall, without waste. There's but one way; that's our way. Make oil grooves around the rings; simple, isn't it?

The grooves convey enough OIL to form the seal, which means perfect compression without WASTE; maximum power with less GASOLINE; perfect lubrication without CARBON, smoke, and oily plugs.

We absolutely guarantee each ring for QUALITY, ACCURACY, and satisfactory service.



One Piece, Low Cost, High Efficiency.

Carbon Eliminated by Controlling the Oil.

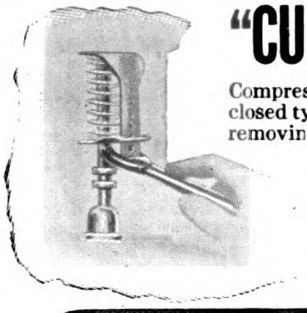
"The Best Accessory Ever Put Out For a Ford Car"

writes the Superintendent of the American Auto Sales Company of New Castle, Pa., referring to the L-A Steady Steerer. It is something no Ford driver would be without after it is once installed, because it becomes an absolute necessity to his comfort, safety and peace of mind.

L-A Steady Steerer FOR FORD CARS

eliminates body side sway and prevents the consequent turning of the front wheels when rounding corners, turning out to pass vehicles, and when driving over rough roads.



Type R fits any standard Ford Car - - $2.00
Type S for use with Ford cars equipped with shock absorbers, $2.50
Attached, 50c extra. Sent prepaid on receipt of price, with directions for installing, if your dealer is not supplied.

IMPERIAL WELDING AND CUTTING EQUIPMENT
OXY-ACETYLENE PROCESS

How About Your Shop?

¶ Oxy-Acetylene Welding and Cutting Equipment has frequently paid for its full cost in one or two days.

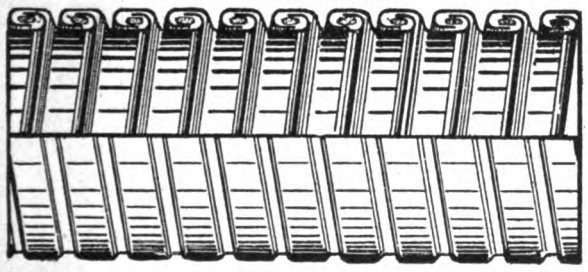
¶ The removal of carbon is, in itself, a big money making proposition.

¶ IMPERIAL Equipment has established a new high standard of EFFICIENCY, because it embodies, to the highest attainable degree, SAFETY, PRACTICABILITY, DURABILITY AND PORTABILITY.

¶ The long, white, incandescent welding flame—free from carbons and oxides—generated by IMPERIAL Torches, has greater efficiency than that of ANY other make, for welding broken castings and metal parts of all kinds.

¶ The IMPERIAL mixing principle, our regulator that accurately controls delivery of gas, from the lowest to the highest pressures, and the fact that ONE torch covers a greater range of work than any other, are exclusive advantages readily appreciated by practical welders.

¶ IMPERIAL Equipment is furnished in a variety of sizes and styles to meet the different requirements of service and our Engineering Department will gladly co-operate with you in the selection of the type best suited to your individual requirements.



Write today for our prices and full particulars.

MERITS

PERFECT CONTROL

Easily installed. Keeps the engine cooler. A secure lock against theft. Fine for kerosening the motor. An absolutely uniform mixture at all speeds. Simple of construction—never gets out of order. Keeps the spark plugs clean—therefore, a hotter spark. Acts as a brake—insures safety in case of accident to the brakes. All adjustments of mixture, to meet varied conditions, made from the seat. Saves *from 25% to 40% on gasoline bills.*

Operating the MICHENER

Why Not Represent Us? We want a reliable man of good standing, in every town where we are not represented, to sell this device. A demonstration of it on your car is all that is necessary to make a sale. Thousands have been sold this way. We ship your orders, prepaid transportation, same day they reach us. Here's your opportunity to make some easy money and to please your friends with an absolutely necessary adjunct to the motor. Sold under 30 days' guarantee. **Let us send you our proposition.**

Quantity production has decreased our cost of manufacture, and the **Michener**—which formerly sold for $6.50 now retails at **$5** Dash Control / Steering Post Control } Insured Post-paid

In ordering, state which side of motor carburetor and steering post are on.

E. S. MICHENER, Jefferson St., NEW CASTLE, PA.

Use Michener's Chain Carbon Remover, the "Carbon Chaser."

ADD POWER TO YOUR MOTOR

by grinding valves easily and accurately without removing piping or wires.

SIMPLICITY VALVE GRINDER

Makes valve grinding a pleasure. Grinds valves the correct way without the weary, dirty, tiring, inefficient results of an effort to use any old grinder. Sturdy—simple. Tight valves mean a cool, quiet and efficient motor. Saves valve-seats, gasoline, time and power. The only scientific ball-bearing grinder, simple and unfailing. Requires only enough pressure to hold valve tightly on seat. Insist on the Just Simplicity Ball-Bearing Grinder.

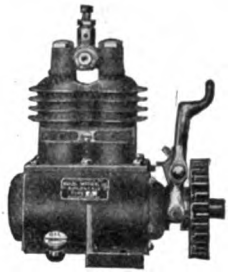
MANZEL
ENGINE-DRIVEN
TIRE PUMP
FOR FORD CARS



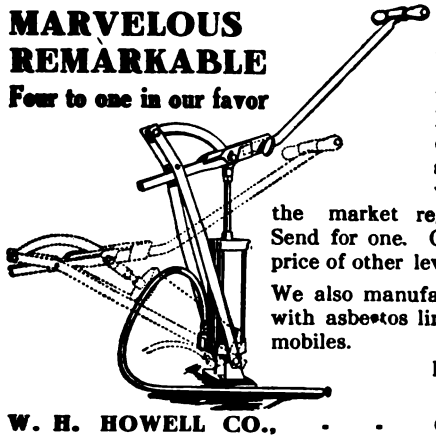
A practical, accurately built, all metal engine-driven tire pump for Ford cars. Will inflate any Ford tire in less than two minutes, and can be installed by anyone. There are no holes to drill or machine work of any kind to be done in making the attachment.

PRICE, $7.50

Complete with steel gears, 12-ft. hose, and pressure gauge.
Everything ready for immediate attachment.

This Is a Money-Maker For You, Mr. Dealer

Every Ford owner will purchase an engine-driven tire pump at this low price, and you can guarantee the Manzel without the slightest hesitation. Tell your customers in the most unqualified terms that we stand behind the Manzel Ford Pump. Let him install it on his car and try it for 30 days. If at the end of that time he is not satisfied, take back the pump and we will make it good.



Two-Cylinder Pumps For the Larger Cars

Our 2-cylinder tire pump which has always sold for $28.00 and $30.00 is now sold for only $20.00, complete with fittings, and we can furnish fittings for over 150 different models of cars.

Write Today for Our Liberal Terms on Both Models

MANZEL BROTHERS COMPANY, 321-323 Babcock St., BUFFALO, N. Y.

MARVELOUS REMARKABLE
Four to one in our favor

The Jensen Lever Pump inflates four tires with less effort than a compound hand pump inflates one tire, It is absolutely the easiest working pump on the market regardless of price. Send for one. Only about half the price of other lever pumps.

We also manufacture Brake Shoes with asbestos lining for Ford automobiles.

Dealers, write for proposition.

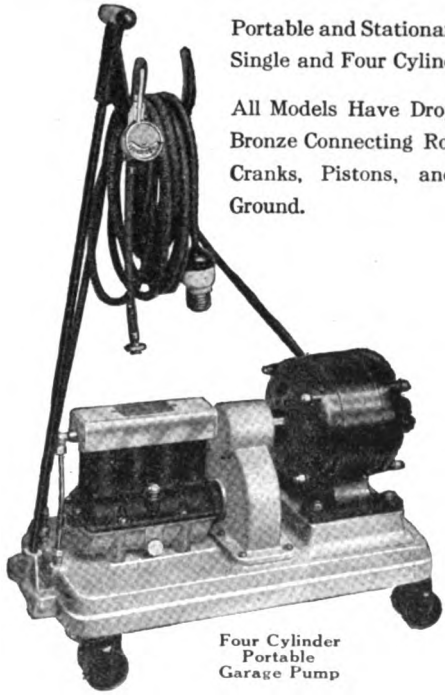
HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES



Don't Pension the Fords, Reborn Them. 1,000,000 Fords must be kept useful cars. THE IMPROVED HEISER CYLINDER REBORING TOOL has opened a wonderful field for the repair man. Reboring and fitting oversize pistons is the most important repair that can be given an engine. It restores compression, eliminates that elusive knock, reduces the fuel and oil bill, satisfies the owner, makes your shop popular, and makes the pistons and cylinders just as new as the day they left the Ford factory. This means that the oldest Ford in point of service will claim its place on the world's highways for years to come.

The time required to make the repair will not exceed 80 or 90 minutes. The tool weighs 45 lbs. and is self-centering, it is not used in connection with a lathe, and you do not rotate your cylinders; anyone without experience can do work that is absolutely perfect to one-thousandth of an inch. Oversize pistons, complete with pin, bushings and rings, $1.50 each.

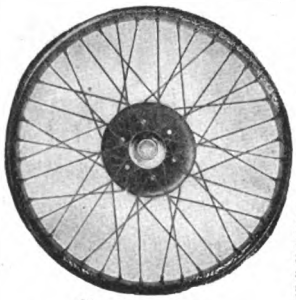
Soak Up the Bumps with the FORDEZER

Registered U. S. Patent Office



For improved riding qualities for which they are responsible are little short of wonderful. Their rapid action permits them to absorb—soak up—the vibration that makes long continued riding tiresome even over city pavements. On rough roads the improvement is even more noticeable. The springs are given a chance to act natural—the snappy recoil which is even worse than the downward bump, is entirely eliminated. The saving it effects in tire expense and car depreciation will more than repay their cost in a season.

Made To Fit All FORD Models

Either Touring or Roadster. They are easily applied. Their construction is the best of any Shock Absorber on the market—absolutely dust-proof; entire mechanism covered with a one-piece drawn shell cover, press fitted to the base. Once a year oiling is all that is required for average use. They will outsell and outwear any other Shock Absorber because all supporting parts are drop forged steel and all moving parts bushed with bronze bearings. The flat section, Vanadium Steel springs are guaranteed for life.

Price per set of four . . . $12.00

Manufactured by
WALKER-MOORE MFG. CO.
Racine, Wis.

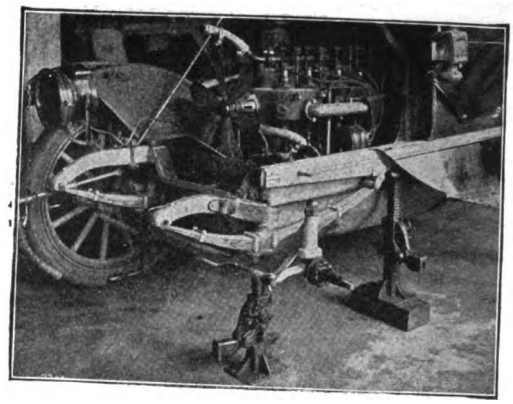
UNIVERSAL WIRE WHEELS

Constructed of the very best material put together by the highest grade of workmanship.

Hubs are of special steel carefully designed as to weight and contour. They are machined to a perfect fit and may be quickly attached to any Ford hub without filing or cutting and the use of no tool except a wrench. Spokes are finest quality wire spokes—rims of heavy rolled stock, electrically welded and heat treated. Finish is black Japan thoroughly baked on—will not chip or rust.

Price per set, $20.00

Manufactured by
UNIVERSAL WELDING CO.
St. Anne, Ill.



The Dewey Power Tire Pump

Save your tire trouble by getting a practical and efficient power pump. Nothing to break or wear out on the Dewey Pump. Every one tested before delivery. Furnished complete with 12 feet of hose, self-opening connections, dial pressure gauge and adapters for any thread spark plug.

Price . . $8.00

Manufactured by
DEWEY-ANDERSON MFG. CO.
Toledo, Ohio

SALES DEPARTMENT
FULTON-McCUTCHAN CO., 1508 Michigan Ave., Chicago, Ill.
(Sold through the Jobbing Trade Exclusively)

A typical automobile repair. Fractured frame before welding.

Shop Cost $7.50 to make this repair by Oxy-Acetylene Welding

Done the old way, this repair would have necessitated almost complete dismantling of the car, heavy expense for labor, loss of valuable time—and in the end, perhaps an unsatisfactory job.

Done with the oxy-acetylene welding process, the repair is made right "on the spot", saving costly dismantling, valuable time and labor—and in the end, the welded part is as strong and neat-appearing as new. In fact, it is sometimes impossible to detect the spot where a weld has been made by this process.

Welding repairs like the above can be made cheaper—yet, at a more substantial profit to the garage man.

Don't pass up this source of legitimate income by turning away welding repair jobs, when you can do this work in your own shop so easily.

Cost of necessary equipment is low. We furnish thoroughly high-grade welding apparatus for $60.00. The average user will also need gas cylinders, at an additional cost, and about $10.00 worth of welding supplies. Truck and special equipment for cutting operations at extra cost.

Users of any other good make of welding or cutting equipment, secure added convenience, usefulness, efficiency, portability and simplicity by using

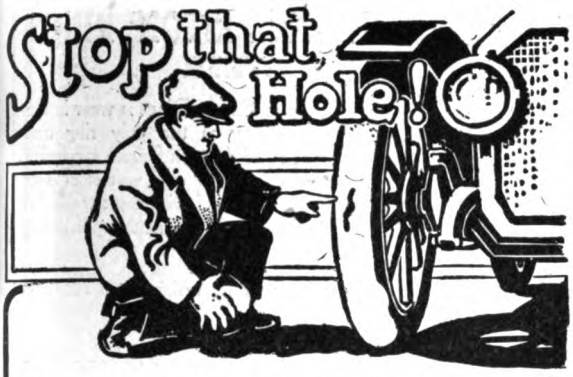
PREST-O-LITE
Dissolved Acetylene

(Ready-made carbide gas)

Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

If you use Acetylene for ANY purpose get full details of the Prest-O-Lite Service Plan.

A New and Highly Profitable Business



Enterprising mechanics, looking for opportunities to engage in a business of their own, should investigate Oxy-Acetylene Repair Work. Immense and growing demand assures a profitable business from the start. Equipment soon pays for itself. Send for particulars.

Your name and address on the margin of this page will bring highly instructive literature. Ask for it.

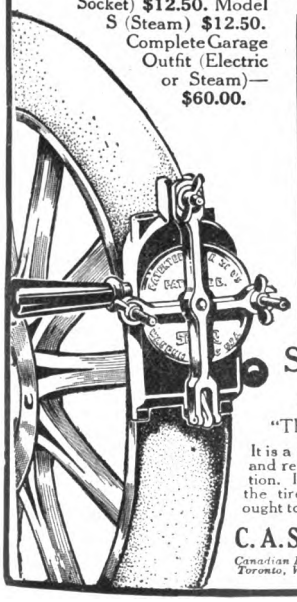
53 direct factory branches and charging plants in principal industrial centers.

Digitized by Google

These little open cuts leave the fabric exposed. *Blow-outs* result, and expensive repairs.

Vulcanize these small holes. Seal them up with a Shaler Vulcanizer. Triple your mileage and save half your repair bills.

SHALER Vulcanizer



A Shaler Vulcanizer will repair any puncture, cut, hole, or tear in casing or tube perfectly and permanently. Has automatic heat control. No danger of undercuring or overcuring.

The Shaler Vulcanizer is the successful result of years of work to make perfect repairs on pneumatic tires by vulcanization.

The Shaler Vulcanizer is recognized as standard. In the big garages and best repair shops throughout the country Shaler Vulcanizers are in use.

We are the world's largest makers of vulcanizers and make the only complete line.

We make Shaler Vulcanizers in every type—Electric, Steam, Gasoline and Alcohol. Shaler Vul-Kit (Gasoline) at $3.50. Shaler Tube-Kit, $2.00. Model D (operates from Electric Light Socket) $12.50. Model S (Steam) $12.50. Complete Garage Outfit (Electric or Steam)—$60.00.

Vul-Kit

$3.50

Can be carried in the tool box for emergency repairs. Does away with patches and cement. Absolutely safe. Burns gasoline or alcohol—an exclusive Shaler feature. No watching, no regulating; simply fill the cut with new rubber, clamp on the vulcanizer—fill and light the generator. Can't overcure or undercure. Handle always cool. Anyone can use it. Complete, $3.50.

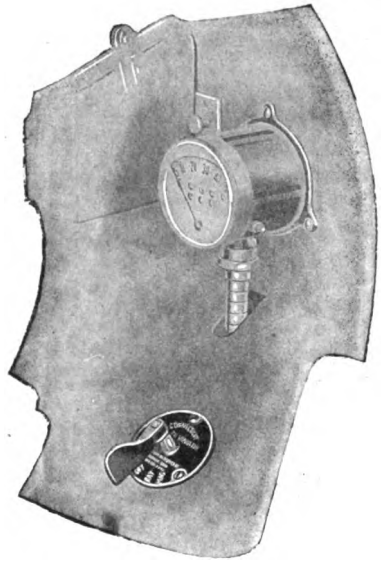
Send for Catalog and Free Book

"The Care and Repair of Tires."

It is a guide and text book on the care and repair of tires. Tells the proper inflation. It describes fully how to protect the tires. It explains everything you ought to know about tires.

C. A. SHALER CO., 802 Fourth St. WAUPUN, WIS.

Canadian Distributors—John Mullen & Son, Limited, Toronto, Winnipeg, Montreal, Vancouver.



The advantages of the

FORD MASTER VIBRATOR CONNECTICUT

More power, greater flexibility and easier starting for your motor.

Freedom from trouble—but one adjustment—unqualified satisfaction.

Economical service and most workmanlike installation.

The CONNECTICUT MASTER VIBRATOR is the only flush dash type Master Vibrator on the market. Nothing shows on the dash but its switch.

The switch lever can be operated by the foot as well as by hand, and the foot-board installation shown above is the most logical solution of equipping 1915 Ford cars with a master vibrator because the standard equipment of coil box, speedometer, lighting switch, etc., does not leave room for the ordinary type of master vibrator.

The removable switch lever, a feature individual to the CONNECTICUT MASTER VIBRATOR, provides a convenient and adequate method of locking your car.

A NEW PRINCIPLE IN PISTON RINGS
UNLIKE ANY OTHER

One of the principal causes of leakage in Piston Rings is wear in the Ring grooves. The **Pressure Proof Ring** is the only ring that automatically takes up the side wear in the piston groove and maintains a tight joint at this point at all times, a feature appearing in no other ring. Oversize rings are not necessary. The self-adjusting feature, which consists of a half round, soft steel wire expander, acting on a bevel on the under side of the ring, eliminates the necessity of accurate fitting in the piston groove. All joints in the **Pressure Proof Ring** are permanently sealed, resulting in high compression and efficiency, preventing carbonization and waste of oil and gasoline.

Made in all sizes, for any purpose. Will work in ported cylinders. No danger of breaking or distorting the **Pressure Proof Ring,** as it is not stretched over the piston in applying. For full information—write the

PRESSURE PROOF PISTON RING CO., 3368 Washington St., JAMAICA PLAIN, BOSTON, MASS.

Why the TRINITY BELL is to be the *ultimate* type of Warning Signal

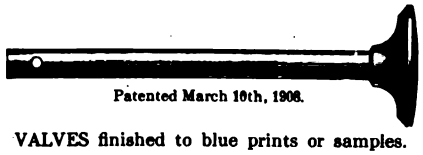
A BELL COMMANDS ATTENTION AS NO OTHER SIGNAL CAN

Bred in the nature of every pedestrian and driver, is the recognition of the two universal danger signals—the bell and the red lantern. Years before motor cars were known, these two signals were standardized—and accepted.

Street cars, fire engines, patrol wagons, ambulances, locomotives, street railway service wagons—vehicles that give the alternative, "move or get injured," are without exception equipped with bells.

Made in 3 models: Model A, for smaller cars, complete, $6. Model B, for medium cars, complete, $10. Model C, for limousines, heavy touring cars and trucks, complete, $12. All prices include entire equipment for installation. Special model for motor boats, $12.

The TRINITY answers all requirements of law, and is absolutely guaranteed. Dealers and Owners: We absolutely guarantee that the Trinity bell is not an infringement on any other similar device.



Dealers and Jobbers—The TRINITY BELL is a big seller at a good profit. Write for particulars now.

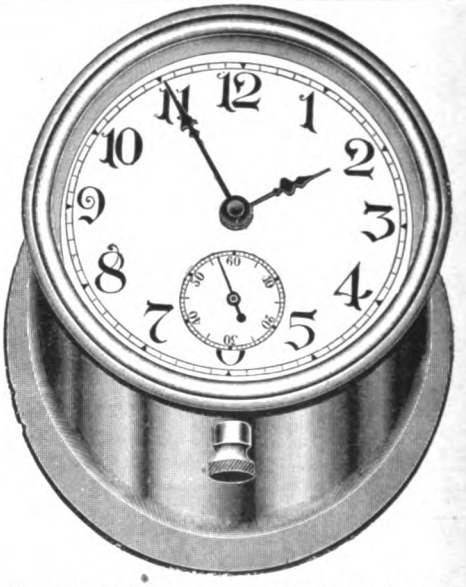
THE ROOT-HEATH MANUFACTURING COMPANY PLYMOUTH OHIO

Every Repair Shop or Garage
SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany**, with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.



The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

Address all orders to

Publishers of THE AUTOMOBILE DEALER AND REPAIRER
71-73 Murray Street, NEW YORK, N. Y.

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3⅜ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

For Leaky Cylinders

Superior to All Others

EVER TIGHT

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

Beware the "Just as Good"

Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.

Jobbers and dealers wanted everywhere. *Write for particulars.*

THE EVER-TIGHT PISTON RING CO.

1428 CHESTNUT STREET ST. LOUIS, MO.

A NEW AND BETTER SHOCK ABSORBER

PATENTED OCT. 2nd, 1914

THIS takes care of spring. Weight is divided in four parts and pulls from four corners.

FOR ANY CAR

This shock absorber will give better service than any other highest priced shock absorber on the market and every part is fully guaranteed.

U. S. SHOCK ABSORBER

FOR FORD CARS

It stands four-square to every car-racking, spring-buckling lurch; not only the straight-away shocks and rebounds but the erratic sways which come in every direction.

$11.00 Per Set of Four

$16.00 Per Set of Two up to 3000 lbs.

$18.00 Per Set of Two from 3000 lbs. and above.

CITRUS

CUBA

Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.

The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.

The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

For literature and further details address the

A **NEW IDEA**

A New Invention

DYKE'S AUTOMOBILE and Gasoline Engine INSTRUCTOR

By A. L. DYKE.

Originator of the first Auto Supplies, Publisher of the first practical book on Automobiles in America.

You learn the PRINCIPLE and CONSTRUCTION of ALL parts of ALL automobiles.

Prepared for the novice, but a handy reference for the expert.

Dyke's Automobile and Gasoline Instructor
Complete $8.50 (add 60c. to prepay)

It teaches the principle of Automobile, Motorcycle, Marine, Stationary and Aero Engines.

HOW TO REPAIR, ADJUST AND DIAGNOSE TROUBLES
Also covers Salesmanship

Every subject is treated, such as **ENGINES**, with all the different valve arrangements, etc. **CARBURETION**—beginning at the simplest form, to the adjustment of all leading makes. **IGNITION**—from low tension coils to high tension magneto systems. **Care of a Car**; Operating a Car; Lubrication, Building and Equipping a Garage, for home or pleasure; Self-Starters—in fact, every subject is fully covered.

VALUE OF THIS INSTRUCTOR TO YOU

WE CLAIM that with careful study of this instructor, it will enable you to become (1) **AN ENGINE EXPERT** capable of diagnosing ignition, carburetion, valve timing, cooling troubles, and remedying them. (2) **A DIAGNOSIST** who from knowing the principle and construction of all subjects, can instantly tell the cause of any trouble and apply the remedy. (3) **A RUNNING GEAR EXPERT** capable of diagnosing and remedying such troubles as differential, transmission, axles, brakes, steering wheels and axle troubles. (4) **AN AUTO MECHANICIAN** who can adjust and remedy all the troubles after diagnosing. The subject of repairing in this Instructor is complete in every respect.

Price of ENCYCLOPEDIA, 600 pages, 1000 illustrations, $3.25 postage prepaid.

FREE—96 page Supplement with 175 illustrations on Electric Starters, Generators, Six, Eight and Twelve Cylinder Engines—with purchase of Auto Instructor.

Supplying the Demand for Raybestos Requires the Largest Plant in the World Devoted to the Manufacture of Automobile Brake Lining.

The recent addition to our plant means more to you than the fact that a new building has been built.

We have just completed an addition to our main factory building which gives us a total floor space of 65,000 square feet—facilities which if housed under one roof, would mean a 5-story building 260 feet long and 50 feet wide.

Here RAYBESTOS is woven, treated, trademarked and prepared for shipment —to the ma.ority of automobile manufacturers as original brake equipment and to nearly one hundred of the leading jobbers in various centers for distribution through the trade for replacements.

It means that the demand for RAYBESTOS is a live demand—a growing demand—a demand brought about by quality and nourished by service.

Merit did this—not sharp merchandising practice.

Because we have been able to improve its quality steadily with the passing years, the demand for RAYBESTOS has grown—in the face of competition—to such an extent that the name

TRADE MARK Raybestos REG. U.S. PAT. OFF.
"THE ORIGINAL AND BEST ASBESTOS BRAKE LINING"

has come to be the term universally applied to good brake lining.

The Royal Equipment Company

WITH FISK SERVICE

FISK NON-SKID TIRES

WITH FISK SERVICE

Now Cost But Little More Than The Fisk Smooth Tread

A remarkable opportunity to secure a strong traction tire, attractive in appearance and of exceptionally good quality at a very slight advance in price over our high-grade smooth tread casing.

Comparative Prices

Sizes	3x30	3½x30	4x33	4x34	4½x36	5x37
Smooth	9.00	11.60	19.05	19.40	27.35	32.30
Non-Skid	**9.45**	**12.20**	**20.00**	**20.35**	**28.70**	**33.90**

The price is new but the tire stands proven in quality, mileage and safety. Its strong, well formed buttons and corrugations grip the wet pavement or muddy road, preventing the dangerous side slip and making sure the quick forward stop in time of emergency.

Go to the nearest Fisk Dealer and see the Fisk Non-Skid Tire. It is the last word in Fisk construction, which means it is the most advanced example of tire building that money can buy. There are Fisk Branches in all principal cities and thousands of Fisk Dealers throughout the country eager to prove to you the broadness and fairness of Fisk Service. Write Dept. 26 for Fisk Literature.

European Motorists get 10,000 to 15,000 Miles out of their Tires

15,000 Miles

American Motorists 5,000 Miles or Less

5,000 Miles

Don't throw away your half worn tires.

There is no longer any reason why you should be satisfied with from 3,000 to 5,000 miles service from your tires when nearly all European motorists and over 20,000 American car owners are getting from 10,000 to 15,000 miles over all kinds of roads. It is just as unnecessary—just as extravagant to throw away your tires when they become tread worn or rut worn as it is to throw away your shoes when the first sole gets thin, for you can get 5,000 miles more service out of them by doing what European motorists have done for the past three years.

What European Motorists Do

The foremost European engineers for a long time studied the problem of getting more miles for less dollars. With their usual painstaking, scientific thoroughness, they experimented for years with leather tire protectors and steel studded treads.

The result—for over three years European motorists have been "half-soling" their tires with steel studded Treads, just as we "half-sole" our shoes when the original sole gets thin. These European motorists are getting from 10,000 to 15,000 miles out of the ordinary pneumatic tires, while American motorists are getting from 3,000 to 5,000, and—what is just as important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim-cuts!

How Does This Affect You?

Figure this out by the individual—how it affects you—your pocketbook.

Every mile you travel on the bare tire is costing you from 1½¢ to 4¢ in tire wear alone, to say nothing of the lost time and expense for the repair of punctures and blow-outs.

Just step for a moment and consider what it **means to you** to get 10,000, 12,000 or 15,000 miles out of your tires and at the same time drive your car without the constant, nerve-racking dread of tire trouble and skidding.

In round numbers it means a saving of $50.00 to $200.00 each year—a saving sufficient to pay your gas and oil bills each month. Yet this saving is not all—the tire vacation and relief from skidding assured you certainly means a gratification which cannot be estimated in dollars and cents.

No More Skidding

Durable Treads are as sure footed as a burro and they're supremely convenient.

They are studded with sharp-edged steel rivets, which dig right down through the mud and slush and get to earth every time. In London and Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of the steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and—what is more important—you receive perfect non-skid service while your tires are protected instead of injured. They cover the tire completely—extending entirely around from rim to rim. Nothing can work its way in between. They afford a perfect protection—that's why we can guarantee them as we do.

Don't Throw Away Your Old Tires

No matter how cut and worn they are, you can get more mileage from them and the few cents the junk man gives you can be turned into dollars.

The strongest proof of the economy of Durable Treads is their unprecedented record of sales; 40% of our business comes direct from recommendations of users; in eight months the sale of Durable Treads increased over 700% in the United States alone.

Where is there an automobile accessory which has received such instant and country-wide endorsement?

Guaranteed 5,000 Miles Without Puncture

Think of it—a 5,000 mile tire vacation—to be able to FORGET tires!

This is a pretty strong statement unsupported, but it's not merely a claim.

Durable Treads are delivered to you under a signed guarantee for 5,000 miles of wear without puncture.

This guarantee is an iron-clad agreement—as good as a government bond—and holds good whether your tires are new or old, tread worn, rut worn or rim cut.

Special Discount Offer

To motorists in territories where Durable Treads are not as yet represented we offer a special introductory discount for advertising purposes equal to the **full dealer's profit.**

We have made some strong statements in this advertisement. Make us prove them. You have everything to gain and absolutely nothing to lose, for all we ask is the opportunity to give you a demonstration at our own expense and risk.

We have a catalog, sample and copy of written guarantee ready to send and it's yours **free** for the asking.

Don't let the tires on your car run another week in "bare-footed" condition—don't wait until you get your next puncture or blow-out. Fill out and mail the coupon **right now** and you will hear from us within a week; no expense and no obligation to you.

BOSCH for FORDS

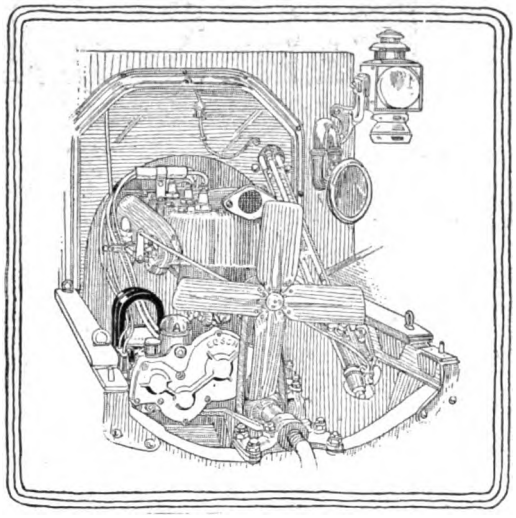
A Necessity—Not a Luxury

A SIMPLE SYSTEM OF IGNITION

—

ONLY FOUR SHORT CABLES

—



A DROP OF OIL EVERY 1,000 MILES THE ONLY ATTENTION

—

THOROUGHLY RELIABLE

—

EXTRAORDINARILY EFFICIENT

ELIMINATES THE SPARK NUISANCE

—

ELIMINATES BOILING OF RADIATOR

—

ELIMINATES PUZZLING IGNITION TROUBLES

—

ELIMINATES VIBRATION FROM MISFIRING

—

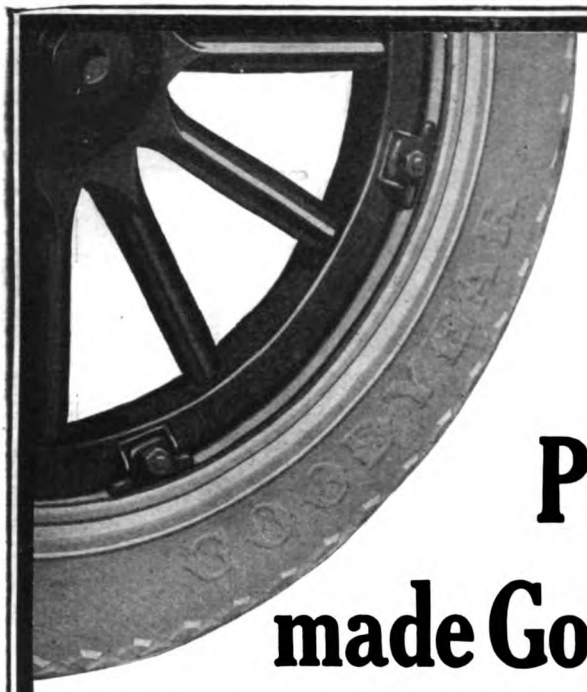
ELIMINATES THE ONE BIG WORRY OF THE FORD CAR

The Bosch-Ford Attachment Installed

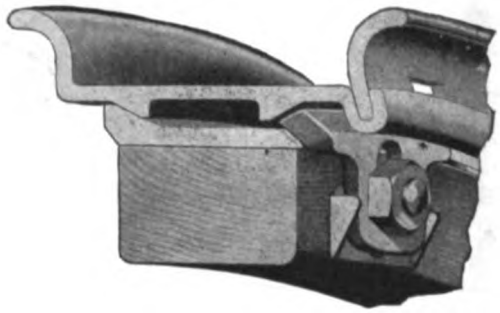
MOST Ford accessories now being offered to Ford owners are luxuries—something added for looks or extra comfort; that's why the average Ford owner isn't sold.

The Bosch-Ford Attachment is a NECESSITY for Fords—not a luxury. It is an accessory that becomes the most important part of the car; it is a necessity because it gets out of the car the life that is built into the car—life, in the form of efficient service and without repair and replacement bills. It is an ignition system that employs the simple but efficient Bosch Magneto of world-wide fame.

The Bosch-Ford Attachment provides efficient and reliable ignition. The weak, irregular spark is no more. In its place occurs a big, fat, arc-like spark that not only gets every ounce of power out of the fuel but does so without straining the engine or car. Unlike other ignition systems, the Bosch Magneto creates its sparks so that each cylinder works in absolute time with every other—there are no uneven power strokes—there is no wear or tear, there is no more boiling of the radiator.



You can have the same ignition system that was used by the winners of the 1915 Vanderbilt Cup and Grand Prize Races, if you fit a Bosch-Ford Attachment. Remember it's a Necessity—Not a Luxury.



—Write today for "The Key to Ford Efficiency"—

Plain Simplicity made Goodyear Rim-Success

Evolution in Rim Design

Constant study and experimenting produced this better Goodyear Rim.

Tires themselves are annoying if they happen to go wrong. But it's the "grief" in changing tires that causes trouble.

Now it's done without hard work by the Goodyear Detachable Demountable Rim.

Goodyear Rims can't stick—won't balk when you want to take them off. And you don't have to "pound them to pieces" when you try to put them on.

They slip off and on as easy as the telling. Simplicity is the keynote of Goodyear Rim-Success.

Take the Drudge Out of Tire Replacing

Tires aren't hard to replace when the rim parts are few and *fit*.

Note these Goodyear points of simplicity—that make easy rim operation.

The detachable side ring makes it possible to remove the tire from the rim without first removing the rim from the wheel. This is impossible with any split type demountable rim.

The Goodyear is a *solid base* rim. It is the lightest demountable rim on the market with the detachable feature. It won't pinch the tube or permit squeaking; it won't allow water and dirt to penetrate and attack the tube—all common faults of split base rims.

The wide rim base is a very distinctive feature. This gives you extra air space—the effect of a larger tire.

Manufacturers Specify Goodyear

Manufacturers are steadily adopting Goodyear Rims. Price is not a consideration with them where car owner's comfort is at stake. Ease of Goodyear Rim operation has won them for their cars.

Yet the cost to car owners is no more than for rims of lesser worth.

Dealers Make Added Sales

Many car owners are troubled by complicated and poorly designed rims. This means a great deal of change-over rim business.

Push these Goodyear Rims. They save in time, in tires, in trouble. They give best satisfaction. They win you a customer—that means his business in the future. They mean attractive profits.

New York Uni-Coil Ignition System for Ford Cars

PRICE $15.00

It gives all the advantages of the best high tension magneto service. The spark is delivered in perfect time to each of the four cylinders. No failure is possible at any speed. Greater power, speed and flexibility is attained by its use.

Operated by the Ford Flywheel Magneto or Battery

It increases the efficiency and perfects the timing of the Ford Magneto to a degree that puts it in a class with the best big-car magnetos. The **vital factors** in **magneto efficiency** are all embodied in its construction—a magneto contact breaker, with but one pair of adjustable contacts—an advanced type of high tension distributor that uses but one of the standard Ford coil units.

The New York Uni-Coil gives the Ford the ignition efficiency of the high-priced cars. It permits unlimited spark advance and assures perfect accuracy in timing at all speeds. It greatly simplifies the Ford ignition apparatus, eliminating the timer and practically all the present wiring. It is readily installed on the car, all necessary fittings and connections being supplied. This equipment includes an **elevating gear bracket which is permanently oil-tight.**

The complete Uni-Coil Ignition System costs $15.00 at retail. Dealers' margin is right—selling terms on request.

DEALERS!

The 500,000 Ford Owners of This Country Form a BUYING PUBLIC That You Can't Afford to Overlook—Here Are Two Ford Necessities That Will Bring Their Patronage Your Way.

The New York Master Vibrator, $10.00

Successful for Six Years on Ford Cars

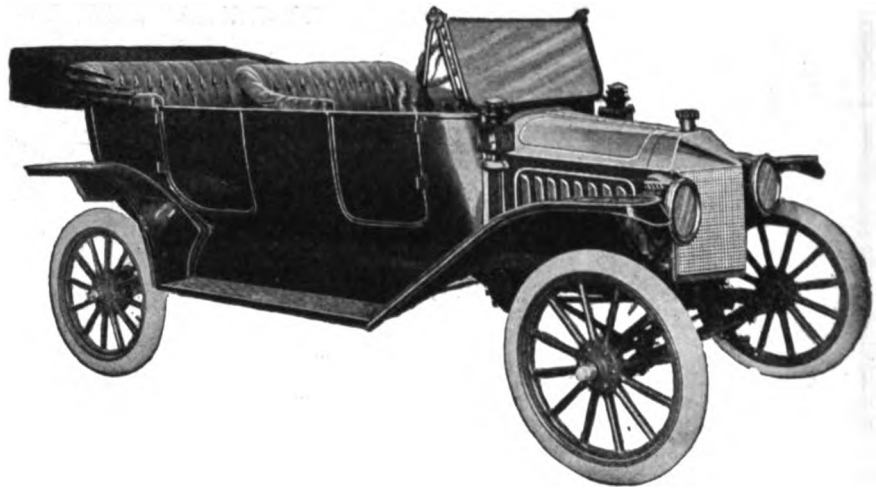
READILY INSTALLED ON THE NEW 1915 MODELS

The "New York" has always led—six years ago Ford owners were enthusiastic about its performance—to-day it is giving satisfaction on thousands of cars, old and new. It was first in the field and has since been imitated many times, but never equaled.

DOES NOT STICK

Requires the Minimum of Attention

The **"New York"** demands less in the way of adjustment and correction than any other type of master vibrator. It practically manages itself. Under all conditions of service it insures a hot, powerful spark, smooth performance and easy starting. It practically eliminates carbon deposits in the cylinders by producing cleaner combustion. Many engine troubles are avoided when the "New York" is installed on a Ford Car.



It pays for itself in the saving of coil replacement expense and in gasoline economy. At $10.00 it is the best "buy" you can offer a Ford owner. Used with our contact points it is good for the life of the car. These are supplied in **sealed red envelopes bearing our name**—the guarantee of quality and efficiency.

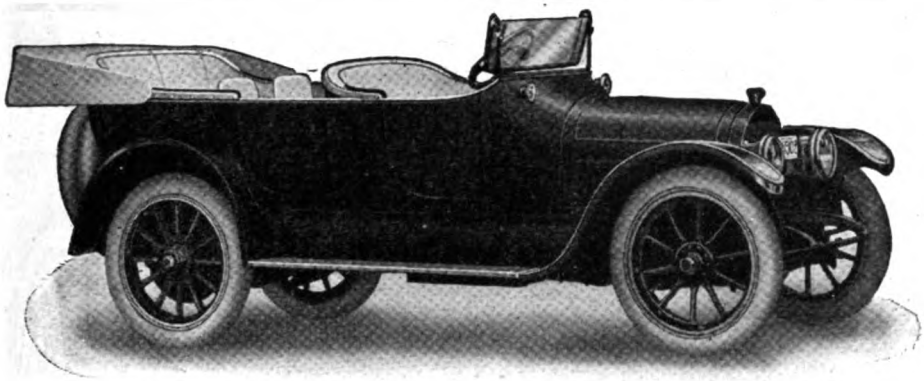
GERMAN SILVER RADIATORS
$5.00 EXTRA

Demand + Quality = Price

Livingston sloping hoods give that long stream line effect so admired in cars of higher cost.
Its sides are ventilated to permit of additional cooling by allowing the heat generated by the motor to escape from under the hood.
We manufacture two types of stream line hoods for Ford cars. One to fit all cars built prior to February, 1915, and one to fit the 1915 model.
With each hood for Ford cars manufactured prior to 1915 a hood ledge for the dash is included.
With the hood for the 1915 Ford a hood lug for the top of the curved dash is furnished.
The hood is waterproof, preventing the water from reaching the motor.
The four hood hooks standard on the Ford car are used without changing their position.
Either stream line hood can be used with Livingston radiators or with the standard Ford radiator, and anyone who can handle a screwdriver can readily change hoods in fifteen minutes.
In black enamel finish only. Can be sent by Parcel Post.

All Livingston honeycomb radiators are guaranteed to cool the Ford motor under all conditions. No matter how warm or how cold the weather conditions, the Livingston will do that which is required of it.
Livingston radiators for Ford cars are not made to compete in price, but rather to give satisfaction long after the price is forgotten.
The Livingston pointed front radiator for a Ford car adds to its style, beauty and individuality.
The construction of the Livingston radiator is entirely different from any other. Livingston tubes are constructed so that the water flows alternately in a horizontal and vertical direction around three sides of each square. This makes the water column exactly twice the height of the water column in any other radiator. Therefore the water is in contact with the air for twice the length of time—hence increased efficiency.
Livingston radiators will not leak due to freezing, as the corrugations on the side of the section give under the expansion of water due to freezing and return into shape when the ice melts.
These are exclusive Livingston features that make for years of satisfied service.



Hundreds of Ford dealers are making added profits by selling Livingston Products. Write for our proposition.

The Ford is not Responsible for Rough Roads

But no matter how rough the roads or how fast you drive you can ride smoothly over every inch of the roughest roads when you equip your Ford car with

TRADE K-W MARK REG U.S.PAT OFF **Road Smoothers**

QUICKLY APPLIED TO YOUR FORD CAR

Give you Ford car advantages, with heavy car comfort

In Buying, Here's What You Must Look For in Order to Combine Comfort, Safety and Economy:

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.
4. No frictional wearing surfaces.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost *twice the length of spring action* or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

$15 SET OF FOUR ONE FOR EACH WHEEL

K-W Bushings

There are no frictional surfaces to wear on K-W Road Smoothers, and all bearings are phosphor bronze throughout. That means long life.

But you can find all of these vital factors only in K-W Road Smoothers.

That is why they lengthen the life of your car, by eliminating shock and vibration. Tire economy is assured, because K-W Road Smoothers enable the wheels (not the whole body of the car) to follow the contour of the road. That means no grinding off the rubber of the tires. K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary, except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your cars' usefulness, and bring you home with "that satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

Dealers: Sell Micro Piston Rings

Pleased Customers and Fair Profits

No man will want old style piston rings when you explain the fuel and lubricant waste, the compression and power loss and the maintenance troubles that result from the gradual opening up of plain ring ends as the rings wear in service.

Show your prospect the good points of Micro two-part pressure-tight rings, as indicated in the diagram, explain how permanent the provision for satisfactory service, how easy they are to apply without danger of **strain** or **breakage**, and you will have made a sale that pays good immediate profit, you will have done your customer a real favor, and you will have stimulated the good-will that prompts buying of more goods.

The mechanical excellence and good engineering judgment back of Micro Piston Ring design appeal on sight, and as our representative, you get liberal discounts, a strong protective guarantee and every co-operation.

Micro Piston Rings
The watchdog of a motor's power.

Your judgment in selecting Micro Rings will be more than vindicated on the first installation and you can make the trial at our risk. Business fairness, extensive manufacturing and rigid inspection to micrometer accuracy put backbone in our guarantee.

If your jobber cannot supply Micro Rings don't accept a substitute and be disappointed. Write us direct.

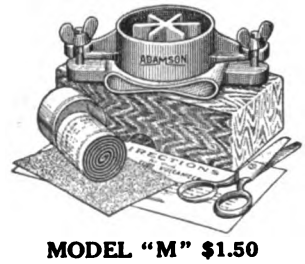
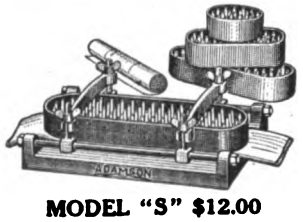
Make good money helping us put an

ADAMSON VULCANIZER



in every touring motorist's tool kit



MODEL "U" $3.00

MODEL "T" $2.00

MODEL "M" $1.50

MODEL "S" $12.00

Here's a great chance to make a nice profit – easily, quickly! Touring season is at hand and hundreds of motorists in your territory are planning trips. Every one of them needs a vulcanizer with which he can make tire repairs at any place on the road!

Sell these men Adamson Vulcanizers

As soon as a customer mentions "trip"—that's your cue to sell him an ADAMSON. Show him how compact it is, how easily operated, how it does not use either steam or electricity, how it requires no watching or regulating, how it works automatically, how it won't burn or ruin tires, how he can use it anywhere and make perfect repairs with little work or expense and he'll fairly beg you to sell him one.

Over half a million in use

The ADAMSON is not an experiment but the most extensively used vulcanizer today. Considerably over half a million motorists carry it in their tool kits—and they wouldn't think of starting a trip without it. It is, however, a distinctive vulcanizer—unlike all others and protected by patents. It is so simple, practical, certain in its operation that nothing equals it. And its price! It's so low that a motorist can't find an excuse for not buying it. It's the cheapest tire insurance obtainable.

We are going after this trade hard and you can cash in heavily if you start **now** to get your share. Write for details of our great selling proposition.

What's the Answer to the Skid Question?

But To Protect You They Must Be On Your Car!

WHEN your car's geared-to-the-road you can put "skid fear" behind you forever.

To drive with confidence and comfort—to have your car instantly obey your slightest touch at the steering wheel—to secure absolute traction on slippery city streets or on treacherous country roads, *you must have a tire that is built to meet those conditions.*

Miller "Geared-to-the-Road" Tires are scientifically built to gear your car to the road through mud, sand or slush. With Miller tires on your car you're in control. Its tread is an integral part of the tire and retains its safety features until the entire tire is worn out. The greater mileage you get from them, will make your choice of

Miller GEARED TO THE ROAD Tires

An economy, as well as a permanent safeguard.

But Miller Safety Does Not Stop There

Miller mileage and safety on the road are due to exclusive methods of tire building in the Miller factories.

The "Miller Method" retains the natural vegetable wax and oil in the cotton fibre during the process of vulcanization. And this natural lubricant in the cotton means less internal friction and more life and miles in your tires.

Wax and oil carbonize at 240 degrees; the old method requires about 287 degrees to vulcanize a tire.

The Miller Method vulcanizes at a low degree of heat without robbing the fabric of its life-giving wax and oil, and thus saves the fibre from becoming brittle and losing its tensile strength. Your Miller tire has not been "burned o t" during manufacture—all its wear, toughness, endurance and all its mileage are preserved for wear on your car.

There are responsible Miller dealers everywhere—write us if you can't locate yours.

A BUSINESS FOR $42

Profits from the Trial Period will pay for it

FREE TRIAL OFFER

If at the end of two weeks' trial in your shop, you decide you do not want the outfit, ship it back to us and we will refund your money IN FULL. No strings to this offer. Not necessary to give any reasons.

COMPLETE WATERHOUSE WELDING OUTFIT $42

Waterhouse Outfit

	Value
1 B Welding Torch with 5 tips	$17.00
1 Oxygen Reducing Valve with 50 lb. line pressure gauge	10.25
1 Acetylene Reducing Valve with 50 lb. line pressure gauge	11.00
1 Set of Special Welding Hose (20 ft.)	3.00
1 Pair of Welding Glasses	.75
1 Carbon Burning Torch	Free
1 Set Instructions	Free
Net Cost Complete - - -	**$42.00**

Rods and Fluxes $4.50

What you get

1 Bottle Aluminum Flux
1 Can Cast Iron Flux
1 Can Copper and Brass Flux
2 Pounds Brass Welding Rods
5 Pounds Cast Iron Welding Rods
2 Pounds Aluminum Welding Rods
2 Pounds of Steel Welding Rods.

With a Waterhouse Welding Outfit, you can do work that no other concern can do unless it has a Waterhouse Welding Outfit. Can be efficiently operated by any intelligent mechanic.

Economy of time, metal, labor and machine and hand work after the welding process.

No aditional space or equipment is required. Needs but a small space to successfully operate on the largest work. Can be placed in a corner or carried anywhere.

Economical because there is no waste of time or fuel—the torch will not flash—it can be used all the time it is needed, absolutely safe.

With every Waterhouse Welding Outfit is given a free carbon-burning torch with which carbon can be removed from the cylinders of any car—an incidental but a substantial source of profit.

If you have a regulator for carbon burning, the oxygen regulator usually sent with the outfit is unnecessary, and a deduction of the price ($10.25) can be made from the price of the outfit quoted.

TERMS: 5% cash discount with order or C. O. D., or $20 cash with order, balance in two payments, first of $12 in 30 days, $10 in 60 days after receipt of outfit by you.

Practical instructions furnished free with every Waterhouse Outfit. These instructions deal with the treatment and repair of all kinds of metal. Be the first owner of a Waterhouse Welding Outfit in your community.

If you do not have at your service a welding shop, we will undertake to make repairs and restoration for prices that will be much less than the cost of new parts.

A REAL PROTECTION AGAINST THEFT

THE NEW YORK KICK SWITCH WITH (YALE) LOCK

PRICE $2.50

Instantly fits the Ford metal or wood coil box. An investment of $2.50 gives you a permanent insurance against loss of your car.

This is a handsomely constructed Kick Switch of liberal proportions, but contains a genuine Yale Lock, which when the key is turned prevents the unauthorized operation of the car regardless of in what position the switch lever is turned. This switch affords the convenience of the conventional kick switch, but possesses the locking feature, which is found in no other type.

Connections are carefully numbered and instructions furnished with every switch are so very plain that not the slightest difficulty will be experienced in installing.

Can you afford to run the daily risk of having your machine stolen when for $2.50 you can leave your car anywheres with a perfect feeling of security and contentment?

At all first-class jobbers or will be sent prepaid upon receipt of price. Subject to return if not pleased.

NEW YORK COIL COMPANY

338 PEARL STREET NEW YORK, N. Y.

THE NEW YORK

Shock Absorber

For Ford Cars

Price $7.00 Per Set of Four

Attached in fifteen minutes without removing the wheels, radius rods, or spring perches. No bearings to wear out or replace, no **tin** covers to rattle loose and become lost, no attention after once installed—which any owner accomplishes in a few minutes by simply removing spring shackles and placing our Absorbers in their places.

Operate in **two** directions and are **perfectly free from all side sway.** They give a luxuriance to the Ford seldom obtainable in the highest priced cars. One very advantageous feature is the fact that the regular fittings supplied on the Ford car are left intact, which is not the case with other **Absorbers.**

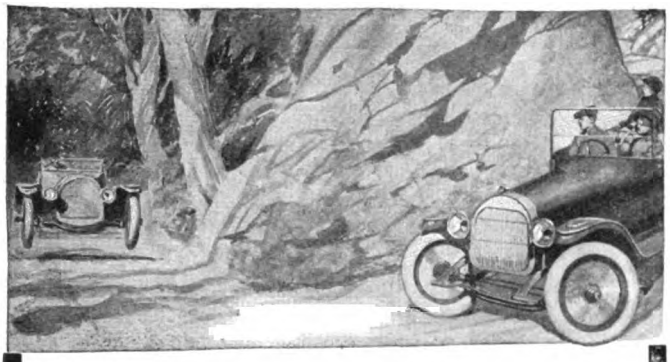
Aside from the labor of installing the **ordinary** Shock Absorber the substitution of other parts not furnished by the Ford Company most always results in **throwing the running gear out of line** resulting in **difficult steering and great wear** on the tires, due to improper tracking of wheels—a condition impossible with the NEW YORK. "They are correct in every way or they would not bear our name plate."

For FORD CARS $10.00

NEW YORK Constant Level Lubricator

Supplies fresh, unused, life-giving oil, maintaining a "CONSTANT LEVEL" of oil in crank case without feast or famine. Oiling starts and stops with the operation of the car positively. Prevents the formation of carbon and ignition troubles, and quickly pays for itself in the saving of oil. Doubles the life of engine and transmission bearings, and is without question the MOST PRACTICAL, MOST POSITIVE, MOST NEEDED DEVICE SINCE THE ADVENT OF THE FORD CAR.

Price $10.00 Complete



Installed in fifteen minutes by the simple use of a wrench.

Easily installed on 1915 Models.

The Hidden Road

A smash-up hurts the reputation of the car and of the dealer who sold it. No one knows how it happened so they blame the car.

What really caused the trouble in most cases was that brake lining failed to grip.

It failed because the brake lining was inferior or worn out—got hard and dry – became friction-shy.

Thermoid
HYDRAULIC COMPRESSED
Brake Lining - 100%

Brake Lining, to be any good at all, must be 100%—must be honest brake lining all through. Not merely on the thin outside surface—not merely a loose and stringy-woven lining that is friction-shy inside.

Thermoid is forced by hydraulic compression into a solid, single substance of uniform density and friction clear through. It retains its 100% gripping power even until worn paper thin.

Thermoid is trustworthy. Guard your safety with Thermoid.

Watch your brake lining.

Cannot be burned out nor affected by oil, heat, water, gasoline, dirt.

Our Guarantee: Thermoid will make good, or we will.

THERMOID RUBBER CO.
TRENTON, N. J.

National Rubber Tire Filler

THE ONLY GENUINE ALL RUBBER TIRE FILLER

It is made of the best grade of rubber, cut in small particles molded to a pattern, properly vulcanized by a special process, laid inside the tire and put on with the same pressure as required by air. No chemicals, oils, glucose, or gelatine to damage your tires; nothing but high-grade Rubber. No limit to its life and wearing qualities. Can be changed from one tire to another as often as is necessary. A perfect substitute for air. Rides just as easy after 30,000 miles as when new. From both a business and pleasure standpoint it is the greatest economical factor ever produced.

TO GARAGE OWNERS

Special Announcement

A new source of big revenue for you is opening up, in the rapidly increasing use of Electrical Starting and Lighting Equipment. With the exception of the very low-priced cars, practically every car now made has this equipment, which includes motor, generator, battery, switches, regulating devices, wiring, lamps.

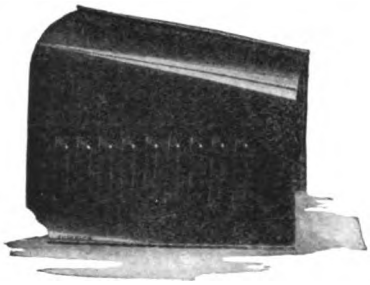
You must have special knowledge and special equipment to remedy electrical troubles and repair starting and lighting equipment. If you go at it by hit-or-miss methods you will drive away your trade, and it will carry with it the general repair and supply trade of all kinds.

ARE YOU A "LIVE WIRE"?

If so, we will make you a special proposition, the acceptance of which will equip you to handle this big new trade far better than your less enterprising competitor, and will give your business a big jump ahead. If you do not accept it, somebody else will and you will lose.

If you want to control the cream of the high-class trade in your territory, write to us at once. We will "put you next" to something worth while.

We are interested only in those garage owners who are enterprising enough to recognize the golden opportunity we will lay before them.



This special offer of ours will be withdrawn very soon, hence we suggest your immediate action.

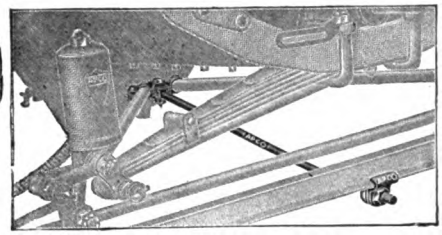
Five New APCO TRADE MARK Specialties

For Sale By All Live Jobbers and Dealers

REAR AXLE TRUSS

The Rear Axle on the 1915 Ford Car has been strengthened about 50% over any previous type, and this is not the first year that improvements have been made on this unit. To strengthen the old cars we offer the APCO Truss which is made from steel rods and semi-steel castings finished in black enamel. The rods are one-half inch in diameter and strong enough to give the axle the stiffness lacking in its original construction. The clamps go around the castings at the extreme end of axle housing, and do not put any strain on the pressed steel parts. The cradle that fits under the center of the housing is fitted with square sockets to accommodate the square heads that are made integral with rods. Bolts for clamps are square headed sunk flush in square sockets to prevent turning and to improve appearance. The whole outfit comes packed in a corrugated box 24" long and weighs 5½ pounds. If your axle housing leaks grease or your rear gears are noisy you need an APCO Truss to remedy the trouble. If not you need the Truss to prevent it. Installation is a matter of ten minutes with no tools but a wrench.

PRICE Complete $1.50



SPRING LEAF LUBRICATORS

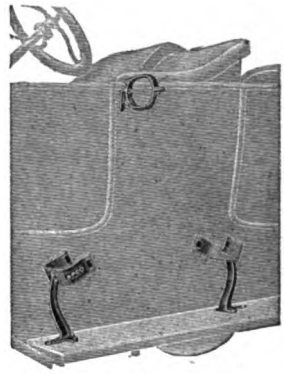
One concern selling an oiling or lubricating device for the leaves of automobile springs spent $20,000 advertising their product during last year. Another spring maker makes great claims for his springs because they are self-lubricating. There is no question about the advantages of having the spring well oiled. It's only a question of the means. The APCO Lubricator as shown in the cut consists of a pair of plates with oil reservoirs and felt inserts. These inserts soaked with oil rest against the sides of the spring leaves and give them constant lubrication which increases the riding qualities 100%. They are made from semi-steel, black enameled and are guaranteed to do the work as well as the highest priced article on the market. Set includes four pairs, two pairs for each spring. The only ones on the market that oil both sides of spring.

PRICE Complete $2.00

FRONT AXLE BRACE

The front radius rod on the Ford is made of tubing in which there is more or less spring or give. This give causes the bottom of the front axle to tip or bend back in going over rough roads, causing an unsteadiness in steering. The APCO brace consists of two ingenious clamps and a half-inch steel rod with a square head made integral. One of the clamps is attached to the extreme end of the front axle truss rod with three bolts, all having square heads to prevent turning, and the square head on the rod is held in this clamp. The other clamp is attached to the front axle and is held there by two nuts on the rod which go thru clamp. This device is one of the best accessories we have ever offered and is one that you need. Finished in black enamel. Can be put on the car with a wrench in five minutes. Packed in a corrugated box 23" long, weighs three pounds. There is no need of adding twenty pounds to the weight and five dollars to the cost of your car when ours will do the work. A new radius rod costs $3.00, you will never need a new one if your car is equipped with an APCO brace.

PRICE Complete $1.50



VALVE STEM PACKINGS

When the valve guides on an engine wear it is impossible to get a perfect mixture as air is drawn thru the space between the valve stems and the wall of the guides. This results in a skip that is impossible to find, especially at low engine speeds and full power cannot be obtained from the engine, as part of the suction stroke is wasted by drawing air by the valve stems. The APCO packing consists of a special steel stamping and felt washer which is held in position by valve spring as shown in cut. When in position the felt both prevents air from entering the cylinders and also lubricates the valve stem preventing further wear. They are necessary on the new cars as well as old, and the installation in either case is a matter of a very few minutes without tools of any kind.

Price per set of Eight 50c

SIDE TIRE HOLDERS

There are so many new rear tire holders on the market that the public is inclined to overlook the good points in favor of a side tire carrier. Absolutely the only advantage of having the tires on the back of the car is that of balance, and as a pair of shoes weighs but 20 lbs. this is purely an imaginary one. There are hundreds of reasons, however, why you should use APCO Side Tire Holders, and the following are a few, any one of which is sufficient for you to decide in their favor. 1. They keep the tires clean. 2. They keep the tires away from the hot exhaust. 3. The tires can be removed in five seconds and replaced in same time. 4. They can not be lost off the car. 5. They are much neater in appearance. 6. They can be installed in ten minutes. 7. With them it is possible to carry a trunk at the rear. 8. They make unnecessary the changing of tail light location. 9. They weigh seven pounds less than the lightest rear holder on the market. 10. There are no straps to lose or break. 11. Price is the lowest of any tire holder on the market, irrespective of advantages. 12. Special catch on top bracket locks automatically when closed and lock need not be used unless wanted. 13. Screws that hold bracket to body cannot be removed with tires in place. 14. Lock is solid brass mail type which opens automatically when key is turned. 15. Lock clasp is rubber covered to prevent rattle. Furnished in black enamel only. Packed in corrugated carton 6"x11"x7½" and weighs seven pounds. Complete with bolts, screws and lock. Will fit two 3½" tires or one 3" and one 3½".

Page Woven Wire Fence Co. *Windshield Department* **Adrian, Mich.**

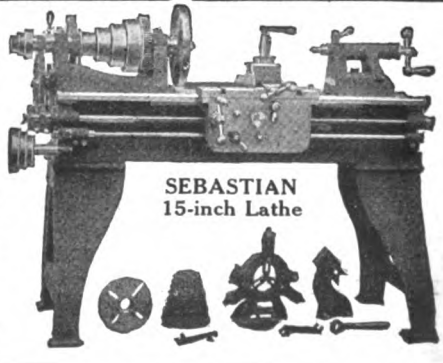
A NEW PRINCIPLE IN PISTON RINGS
UNLIKE ANY OTHER

One of the principal causes of leakage in Piston Rings is wear in the Ring grooves. The **Pressure Proof Ring** is the only ring that automatically takes up the side wear in the piston groove and maintains a tight joint at this point at all times, a feature appearing in no other ring. Oversize rings are not necessary. The self-adjusting feature, which consists of a half round, soft steel wire expander, acting on a bevel on the under side of the ring, eliminates the necessity of accurate fitting in the piston groove. All joints in the **Pressure Proof Ring** are permanently sealed, resulting in high compression and efficiency, preventing carbonization and waste of oil and gasoline.

Made in all sizes, for any purpose. Will work in ported cylinders. No danger of breaking or distorting the **Pressure Proof Ring,** as it is not stretched over the piston in applying. For full information—write the

PRESSURE PROOF PISTON RING CO., 3368 Washington St., JAMAICA PLAIN, BOSTON, MASS.

SEBASTIAN LATHES
HIGH QUALITY LOW PRICES



If you delight in good tools, you will delight in Sebastian Lathes. For 25 years we have built lathes, and lathes only, employing skilled labor always, and improving equipment and machinery every year. Sebastian Lathes are

STANDARD FOR QUALITY---LOW IN PRICE

They are accurate, economical, simple and durable. Many re-orders and voluntary letters from users of Sebastian Lathes prove this.
The Sebastian reputation is back of every Sebastian Lathe. You are judge and jury when you buy a lathe. We are not satisfied until you are. Look over the complete line in our new catalog. It shows Lathes for general repair work, garage and automobile work, etc.

When you buy a lathe, say "Sebastian"

Look for the name LEAK-PROOF stamped on the Ring

The Cost of Carbonization

CARBON deposit is more than merely an annoyance. It is an evil—and an expensive one.

¶ It prevents proper seating of valves and causes piston rings to stick—result, poor compression and wasted power. It causes pre-ignition of the fuel charge and premature explosion that entails severe strain upon the crank shaft bearings. ¶ Carbon deposit is caused by incomplete combustion of the fuel charge and by the burning of surplus lubricating oil in the cylinder head. The only cure for both such conditions is

MADE IN ALL SIZES **LEAK-PROOF** EASILY ADJUSTED

Piston Rings

Made by McQuay-Norris Mfg. Co.

¶ They make full compression certain and prevent all passage of oil, because the mechanical perfection of their design ensures proper and continuous bearing on the cylinder. They have no unsealed openings like the ordinary ring, nor the unequal tension of either the eccentric or concentric one-piece ring, nor the weakness of the multiple-piece ring.

¶ LEAK-PROOF Rings are simple, strong, wonderfully elastic—easy to adjust. Each ring is composed of two concentric "L" shaped sections closely interlocking—this is the patented and individual LEAK-PROOF feature. The perfect fit and finish of every ring ensures the minimum of cylinder wear.

When your car is overhauled have LEAK-PROOF Piston Rings installed.

Send for FREE Book—"To Have and to Hold Power"

It explains the theory and function of piston rings. It tells about the LEAK-PROOF **Ring** and why every motor should be equipped with them. How it will pay you in fuel economy and prolonged motor life. Write for it.

Your Old Car Is Worth Ten New Ones

if you only *know how* to cash in its possibilities in Family benefit.

With your permission we propose to *show you* thru the coupon below:

To many Automobile owners it may sound strange when we state so emphatically that Automobile Tours with parties of men, women and children (of any age), over any desired distance, may be made with far greater Safety, Comfort and Pleasure than is possible when traveling in Pullman parlor trains, but we do mean it and will prove it.

Have a Family Picnic Every Touring Day.

The desirable advantage of exclusiveness, independence and unexcelled sight-seeing possibilities while traveling by Automobile, saying nothing of reaching the far out-of-way places so entirely impossible to the railroad traveler, are the points of advantage universally admitted by everyone and need no mention here.

The detail that is not so generally known, however, is: How to equip a car to eliminate excess baggage and useless expense but still maintain every comfort and pleasure of the boulevard spin for each and all the passengers throughout the entire tour. Many car owners who have had reverse experiences, or, say road disappointments, may be a little skeptical because they failed, but we want every reader to be absolutely assured that all past failures have not been without real reasons.

Our experts are past masters in Touring, and after crossing and re-crossing the continent many times, touring and camping with their wives and children, their experience has eliminated many common errors, and like almost everything else in this life, there is a right and wrong way to start. In Automobile touring the right way happens to be much the easiest and far less expensive. We will be only too glad to help all interested Automobile owners for whom a special number of the SERVICE NEWS will be issued June 1, 1915, and copies promptly mailed to all applicants sending in the coupon request.

THE CANVAS TREAD TIRE

With its many layers made of rubber and rubberized canvas impregnated with tread stock in such a way that each layer is woven to the other with rubber and afterwards vulcanized, which makes a stronger and more serviceable tread than the all-rubber tread heretofore used. These layers will not separate, peel off, crack, split, or chunks come out, like the all-rubber tread by the constant vibration. All of these layers are non-skid, but yet a smooth tread, and each layer as they wear off becomes a non-skid and so on until the entire tread is worn out. It takes more than 1,500 miles to wear off one layer. Count the number of non-skid layers and you will see that this tread is good for more than 10,000 miles. It is a tougher tread and more serviceable than heretofore used in other makes of tires. It is the only non-skip tire all the way through ever made, no chains are necessary. It is what is known as a fast tire and takes less engine power and 25 per cent less gasoline. It is free from punctures, stone bruises and never gives any trouble. Try one of these tires with any other tire, which will quickly convince anyone. We only use the most expensive material that goes to make up a tire. If you paid us a $1,000 for a tire, we could not make a better one, because better material is not made. This tire is backed up by the highest percentage of mileage guarantee.

Send for booklet telling many other features and agent's proposition.

IMPERIAL WELDING AND CUTTING EQUIPMENT
OXY-ACETYLENE PROCESS

QUALITY

Meets Any Emergency!

In the shop or on the road – for welding cracked cylinders, broken aluminum cranks, transmission cases, crank shafts, frames, axles, rear axle housings, steering knuckles and all other automobile parts quicker, more effectively and *considerably cheaper than you ever have done before.* Imperial Equipment pays for itself in one or two operations. Safe, compact, reliable, portable; can be moved anywhere – *always ready.*

You Too, Can Do This!

This picture has money-meaning value to garage men. A broken axle out on the road—five miles from a repair shop. Instead of hauling the car back to the shop this progressive garage owner puts his Imperial Outfit and an oxygen tank in his runabout—drives quickly to the job—hitches it to the acetylene tank used for lighting—and *in a few minutes* the axle is as good as new, *without dismantling car.*

Imperial Equipment is indispensable in the garage.

Write Today!

Ask for prices, catalog and full details. *Prove to yourself* how you can save enormously in time and money with Oxy-acetylene Welding and Cutting Equipment.

For Leaky Cylinders

Superior to All Others

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

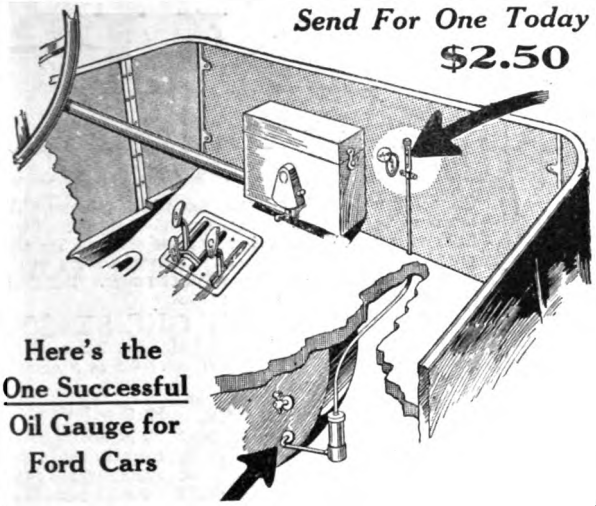
Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.



Jobbers and dealers wanted everywhere. *Write for particulars.*

To Get the Most Out of a FORD

In order to get the best results out of the Ford engine the magneto must be kept at its original high efficiency.

The whole ignition system depends upon the magneto, and even though the engine will run, the magneto may be so weak that combustion is incomplete, thereby wasting fuel, causing cylinder carbon, and slowing up the engine. The only way to know what the magneto is doing is to use

The Hoyt Magnetometer

This rugged little instrument goes on the dashboard and shows at all times the strength of the magneto. The Ford Magneto may be kept at high efficiency by reasonable care and attention, and should never need replacing. Magnetometer methods will keep it right.

You sell the instrument for $4.00. Send for trade prices and our Booklet No. 2, describing Ford Magneto and ignition troubles and remedies.

CITRUS
CUBA

Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.

The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.

The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

For literature and further details address the

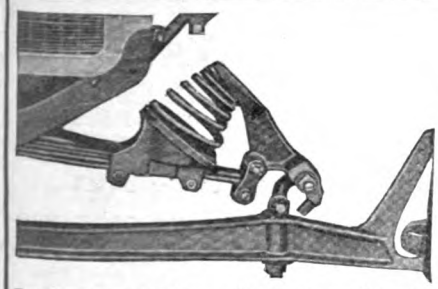
Why the TRINITY BELL is to be the *ultimate* type of Warning Signal

A BELL COMMANDS ATTENTION AS NO OTHER SIGNAL CAN

Bred in the nature of every pedestrian and driver, is the recognition of the two universal danger signals—the bell and the red lantern. Years before motor cars were known, these two signals were standardized—and accepted.



Street cars, fire engines, patrol wagons, ambulances, locomotives, street railway service wagons—vehicles that give the alternative, "move or get injured," are without exception equipped with bells.

Made in 3 models: Model A, for smaller cars, complete, $6. Model B, for medium cars, complete, $10. Model C, for limousines, heavy touring cars and trucks, complete, $12. All prices include entire equipment for installation. Special model for motor boats, $12.

The TRINITY answers all requirements of law, and is absolutely guaranteed. Dealers and Owners: We absolutely guarantee that the Trinity bell is not an infringement on any other similar device.

Dealers and Jobbers—The TRINITY BELL is a big seller at a good profit. Write for particulars now.

The New Schrader Quick-Acting Dust-Cap

The operation of testing the air-pressure in tires having been found on occasion difficult and irksome by reason of the jamming together of the valve stem and dust cap, the firm of A. SCHRADER'S SON, Inc., have designed and placed on the market a new "Quick-Acting" Dust Cap which can be removed from the valve stem by a simple quarter turn.

The new SCHRADER "Quick-Acting" Dust Cap eliminates the work of screwing the cap down the entire length of the valve stem to the felloe of the wheel. All that is necessary is to slip the cap over the valve and turn it one-quarter turn. This locks it securely to the valve stem. To unlock, simply give one-quarter turn in the opposite direction.

PRICE 40 CENTS
$2.00 Per Set of Five

AUTOMOBILE LUBRICATION.

Testing for the Flash Point and the Ignition Temperature.

BY SYDNEY F. WALKER, M. E.

There is a difficulty here as to testing the viscosity at higher than normal temperatures. A test at a temperature of say 70° F., everything being kept at that temperature, will be a certain guide; but it is much better to have also a test at higher temperatures, at least up to that of boiling water. The writer suggests that this again would not be difficult. The inclined plane might form the upper surface of a small boiler, as suggested in Fig. 22, and the water might be raised in the boiler, to any temperature desired, up to boiling point; and by adding the equivalent of a small safety valve, so that the pressure could be increased above boiling point, the temperature of the plate could be increased up to 300° F. or so, with perfect safety. Fig. 23 shows a similar apparatus heated by an electric current. The inclined plane in this case would of course be of metal; and the writer suggests that it would probably be best to have the inclined plane in any case of metal, preferably of copper, as its surface is more easily kept in the same condition. By using a copper plate also, a certain range of temperature could be obtained, by fixing a Bunsen burner under the plate, and heating the plate up. Fig. 24 shows this suggestion. Of course the above suggestions are very crude; but they are intended as workship guides. In manufacturing and repairing works, except in the case of very large establishments, there is not room for a separate testing plant; and the prices obtained for the work usually will not allow of the expense. On the other hand, it is of the utmost importance that every manufacturer of an automobile, every dealer in automobiles, and every repairer of automobiles, should have some method of testing oils that are offered to him, and of ascertaining quickly, whether they are suitable for the engines that are going through the works; the engines that a dealer is selling, or the engines, etc., that a repairer is handling. Probably the above suggestions will only be in the light of what Americans so expressively call "pointers," to mechanics and others employed in automobile work. An idea once mooted, is capable of being carried out in a number of different ways. Every manufactory, every dealers' warehouse, and every repairing establishment, has its own features; its own way of doing everything; and once the idea is given, it is probable that it can be worked out by those on the spot, in such a manner as to enable tests to be made quickly and well.

The writer understands that one large firm of motor car builders in France have practically acted upon the lines of his suggestions given above, but with their own laboratory appliances. They tried every lubricant that was offered them, some 300 in all, and then, none of those offered satisfying their requirements, they thrashed the problem out themselves, making their own blend.

As everyone who buys oil knows, travelers in oil are the most persuasive of individuals. In the old country, numerous jokes are made about oil travelers, and numerous tales are told of their persuasiveness, and of their methods of getting hold of the boss. There are so many of them on the road in the United Kingdom, that managers of works who must use oil, but who are necessarily busy men, fight shy of them. Securing orders for oils is by no means an easy matter, owing to the keen competition among oil firms, and particularly among oil travelers; and it has led to the development of what

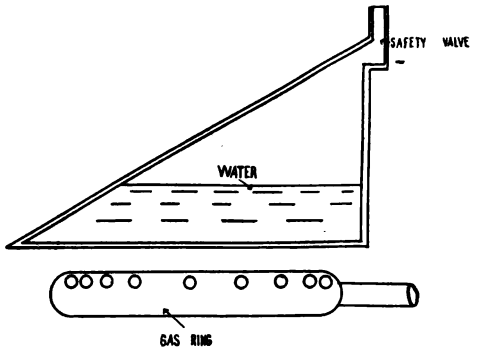

Fig. 22.—Diagram of a metal inclined plane, arranged for testing the viscosity of oils, the inclined plane being heated by a boiler formed under the plate itself, and the boiler being heated by gas.

may be termed a race of oil travelers, whose persuasiveness, and ability for securing interviews, is almost superhuman. Such tales for instance as the following are common in the old country. The principal office of a very large firm of coal owners, was as usual at the shipping port, and their manager, a somewhat fussy individual, and also fairly snobbish, was seated in his room. An oil traveler was the very last man to whom he would have given an interview, but happening to go out of his room for an instant, he found a very venerable looking gentleman, beautifully dressed, with a silk hat polished almost so that you could see your face in it, his coat, boots, tie, etc., of the latest fashion, yet with absolutely nothing of the dude, or man of fashion about him; and with everything about him speaking of the comfortable commercial man, the man who had evidently come to give an order for a good many thousands of tons of coal. Before the snobbish little manager knew what he was about, he had bowed the elderly gentleman into his private sanctum, had shut the door from all intruders, had taken precautions not to be disturbed, and then turned round beaming upon his supposed customer. His surprise and rage may be imagined, when the eminently respectable "buyer" (?) produced samples of oil.

Digitized by Google

The writer believes that the snobbish little manager actually gave that man an order.

Another tale that may perhaps be interesting, that was told the present writer by the manager of another large firm of colliery owners in the Midlands. He went one day to visit a brother manager at another colliery. As he passed the manager's office, he saw him sitting at his desk; but when he reached the office, he was assured that the manager was out, and all sorts of proofs were given him that he had gone down the mine some little time back. By a lucky chance, the writer's friend happened to know one of the men in the outer office, and told him who he was. "Oh! Mr. ———, the manager will see you of course; he thought it was one of those oil men; you are very like him."

The Flash Point.

The flash point is usually made a great deal of, and particularly by oil travelers. One of the first things a persuasive oil traveler will state is, that the flash point of his lubricant is a certain figure. He is usually perfectly safe in saying this, as very few users have any means of checking his statement. The actual flash point is a matter too that oil manufacturers, and oil blenders, are very much divided over. Some recommend a lubricant of high flash point for internal combustion engines, including of course motor car engines, while others maintain that with too high a flash point there is a greater tendency to the deposit of carbon than with a lower flash point.

By flash point is meant the temperature at which an oil gives off sufficient vapor to ignite momentarily, on the introduction of some source of heat of sufficiently high temperature. Like so many other qualities, the flash point may be almost any figure, within certain wide limits, unless special precautions are taken to confine the oil that is being subject to test, and to screen it from all outside influences. As readers hardly need reminding, when any oil burns, as it is called, it is not the oil itself, in its liquid state, that enters into combustion, but the vapor which is given off from its surface. Everyone who has used oil lamps, and even candles, is familiar with the fact that it requires a little time before the lamp, or even the candle will ignite, after the flame of a match has been applied to them. The reason of this is, that a certain quantity of heat must be delivered to the fat or oil, in order that a certain portion of it may be converted into vapor; and it is this small quantity which ignites; and its continued burning liberates sufficient heat to keep a certain quantity of vapor constantly coming away.

The flash point must be carefully distinguished from the ignition point, or the temperature of ignition. The flash point is really that temperature at which the lamp, or the candle, would commence burning; but for testing purposes, the quantity of vapor that is present and that is ignited by the flame or the spark, is even less than that which is given off by the oil in the wick of a lamp. When an oil is to be tested for its flash point, heat is applied to it, and the emission of vapor is watched for, and is known by its temporary ignition. It is a flash that is sought for; hence its name; not continuous burning. The object sought for in the test, is the temperature at which vapor commences to be given off.

A little consideration will show, that the surrounding conditions will vary the temperature at which vapor commences to come away, and therefore the temperature at which a flash is obtained. Suppose for instance that a certain quantity of the oil to be tested is exposed in a shallow tin, whose surface is open to the atmosphere; and suppose that it is a very cold day, and the vessel in which the oil is held is in the way of a draught of air. It will easily be understood, that the vapor will have very little chance of accumulating in the form required to give the flash. The liquid will have to be raised to a comparatively high temperature, before the vapor comes away in sufficient quantity to give the

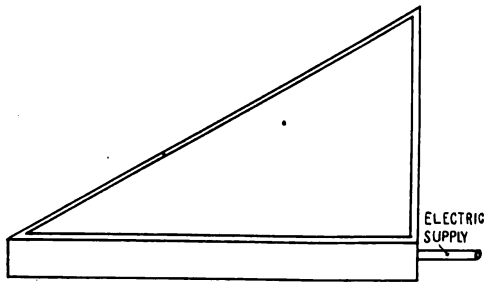

Fig. 23.—Diagram of inclined plane and boiler heated by electric current.

flash test. On the other hand, on a warm day, and if the oil is contained in a comparatively deep vessel, say a tube, the whole thing being in a room where the temperature is fairly high, and where draughts are excluded sufficient vapor will come away very much more quickly, from the same oil, when heat is applied; and therefore at a much lower temperature.

To meet these difficulties in the United Kingdom, various petroleum testers have been introduced. The first one was designed by the late Sir Frederick Abel, who did a good deal of work in the examination of the properties of petroleum. In all of them, the oil to be tested is placed in a vessel, in which a thermometer can be immersed; the vessel containing the oil being enclosed inside another vessel containing water. It is also arranged that a thermometer can be used in the water vessel. It will be evident that the water bath, which is a very old chemical appliance, enables any temperature of the oil to be obtained, that may be desired; and it also enables the temperature to be under control. Great care is necessary in carrying out the test. The apparatus is so arranged, that all draughts are excluded, and the small quantity of vapor first coming away, and forming the flashing test, is caught, so to speak, by the ignition apparatus. One of the best arrangements, in the writer's view, is the invention of an American, and is shown diagrammatically in Fig. 25. In this apparatus there is a metal bath, as shown, standing on feet, and having a cover with a hole in it. In this hole in the cover is placed the oil vessel, which is merely a cup with a lip and a cover. Arrangements are made for inserting thermometers in the water bath and the oil cup. The water bath is raised to 100° F., then the oil cup having the oil in it up to a certain line, is placed in the bath, and the lid closed, the thermometer being exposed outside. The temperature is gradually raised 5° F. at a time, by heating the water bath and the vapor present on the oil cup, if any is given

Digitized by Google

off, ignited by a spark passing between two contacts in the vapor space. The tester closes the circuit sharply with a Morse key, and quickly reopens it, each time a test is to be made. It will be remembered that the atmopshere has the property of absorbing vapors; and that its ability to absorb them increases very rapidly with its temperature; but it also depends upon the tension of the vapor already present in the atmosphere. Not a great deal has been done in the way of investigating the ability of the atmosphere to absorb the vapors of oil; but a very great deal has been in connection with the absorption of the vapor of water; and it may be taken that while the quantity of vapor of different oils that can be absorbed varies, and is different from that of water, the same general conditions hold. In addition to the fact that the capacity of the air for absorbing vapors rises rapidly with the temperature, the quantity of vapor already present in the atmosphere, also has an important bearing upon the subject.

The quantity of vapors of all kinds that the atmosphere can absorb at any temperature is fixed; and as that quantity is more and more nearly approached, the ability of the atmosphere to receive vapor from any liquid from whose surface evaporation is taking place, decreases. It is usual to put the matter in this way. The vapor which is issuing from any liquid has a tension of its own, depending upon the temperature to which the liquid is raised. On the other hand the vapor which is present in the atmosphere has also a tension of its own, depending upon the saturation, the percentage of the possible quantity the atmosphere can absorb at that temperature. Of course in matters of this kind, the ability of the atmosphere to absorb vapors is measured by the quantity that a cubic foot of the atmosphere can absorb; the particular cubic foot of course being stationary. As the quantity of vapor present in the atmosphere surrounding the testing apparatus increases, so does the vapor

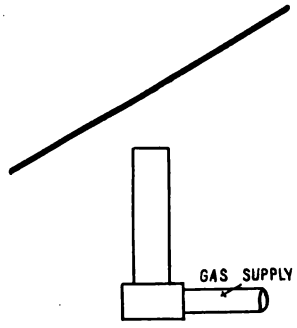

Fig. 24.—Diagram showing a copper plate, as an inclined plane, heated by a Bunsen burner arranged for testing viscosity of oils.

tension; and therefore the ability of the atmosphere to receive vapor, decreases. We are all familiar with the barometer, principally as a guide showing what the weather is likely to be. We say when there is a high barometer, that the weather will probably be fine; while with a low barometer it will probably be wet. The meaning of this is, that with a high barometer, there is very little water vapor present in the atmosphere; while with a low barometer there is a good deal. The vapor of water and the vapor of oils, are usually lighter than air; and so as the quantity of vapor absorbed by the atmosphere increases, so does the barometric pressure decrease. The varying barometric pressure is made use of in correcting the observed flash points of oils.

The test for the flash point is one that can hardly be imitated by any rough and ready apparatus, such as those which have been suggested for other

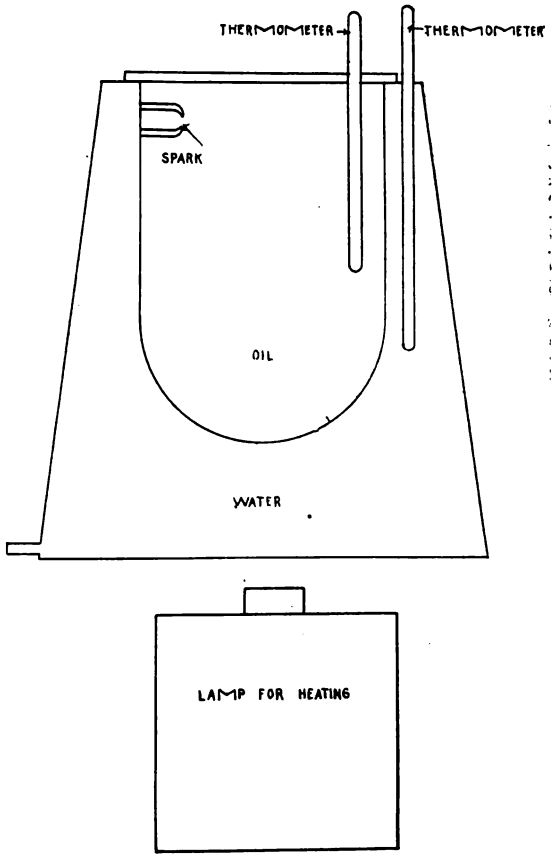

Fig. 25.—Diagram of Saybolt flash point testing apparatus.

tests. It is also very doubtful whether as mentioned above, the flash point is of really any great value, though so much is made of it.

As mentioned above, the flash point must not be confused with the temperature of ignition. The temperature at which an oil ignites under the conditions ruling say in the crank chamber, or in the cylinder, is of great importance. If an oil is employed as a lubricant for instance whose ignition point is below that to which the cylinder walls, or the walls of the crank chamber may be raised, the lubricant will be burnt in place of acting as a lubricant. It should not be forgotten, of course, that all of the substances that are used as lubricants are combustible, and that it is only a question of providing the necessary heat, and the necessary temperature, for them to be burnt up; and for them to leave carbon deposit behind them. It is for this reason that many oil blenders lay such great stress upon the point, that too low a flash point should not be allowed.

By the temperature of ignition is meant of course, the temperature at which the oil will go on burning, just as it does in a lamp.

Again, in the lamp it will be remembered, the

Digitized by Google

heat given off by the flame, causes a portion of the oil to be converted into vapor, the oil for this purpose having ascended the capillary spaces in the wick, and being formed into vapor at the outer surface of the wick. In order that the oil shall burn continuously, the temperature must be maintained at a certain figure, and this is known as the temperature of ignition. The temperature of ignition is necessarily higher than the flash point; and it is also subject to the surrounding conditions. The temperature of ignition, or to put it in another way, the amount of heat required to be delivered to the oil, in order to maintain combustion, would be greater, when the oil was exposed to a cold draught for instance, than when enclosed within the comparatively hot crank chamber, and the much higher temperature behind the piston.

(To be continued.)

MAGNETO AND BATTERY.

Some of the Characteristic Qualities of Each and Wherein the Magneto Is Superior.

From A. Henry, Illinois.—Electric lighting and starting equipment as a whole has become so thoroughly developed that its proven reliability, efficiency and self-sustaining qualities make it almost indispensable in the modern automobile.

As a natural result, most car buyers are insisting upon its incorporation in their machines, and the production and marketing of such accessories have become firmly established features of the automobile trade.

The competitive features of such marketing, as also an ill advised attempt to make a short cut through the mazes of initial and final costs, have in some quarters introduced a disregard for the high practical values of certain ignition functions long since proven through costly experience to vitally affect engine efficiency, reliability, consistent operation, and the best all round satisfaction.

In order to add the talking point, "multiplicity of functions," as an aid in the selling of their products, some manufacturers of starting and lighting equipment provide at very little additional cost either battery-transformer or combined battery-and-dynamo-transformer ignition-equipment to their outfit. Also, some automobile manufacturers, forgetful of past experiences, adopt such ignition equipment, but solely as an aid in the frantic scramble to reduce to the lowest possible figure the first cost of their cars.

Superficially, it appears to such manufacturers and to the inexperienced buyer as well, that the slightly higher cost of a thoroughly reliable true high-tension magneto is no longer desirable, seeing that starting and lighting equipment necessarily involves the use of a relatively large capacity storage-battery, this being recharged at all times when the engine is running, and which, with merely nominal operating care, never runs down to a point rendering it unfit for use in connection with a transformer or step-up ignition equipment.

The palpable error of such reasoning, however, may be easily proven by a little investigation of the modern trend of magneto and automobile engine design and construction, as also of the characteristics of the various forms of "transformer" or "step-up" equipment as compared to those of the "true high-tension magneto," these being considered electrically, mechanically, and from the practical operation standpoint.

Engine Characteristics.

The modern trend of automobile engine development, not only in the pleasure car field, but for the majority of trucks as well, is toward the small-bore, multi-cylinder, high-rotative-speed engine; which development is progressively rendering less necessary or desirable any provision for battery ignition, even for starting, in connection with the true high-tension magneto, when such magneto is applied.

It is now entirely feasible and practical to eliminate from the ignition equipment all provision for battery starting, depending entirely upon the "independent" H. T. magneto for starting by hand-cranking four-cylinder engines of four inches bore or under four-cylinder engines of three and five-eights inches bore or under, in the pleasure car field where the ladies often do the cranking; and in

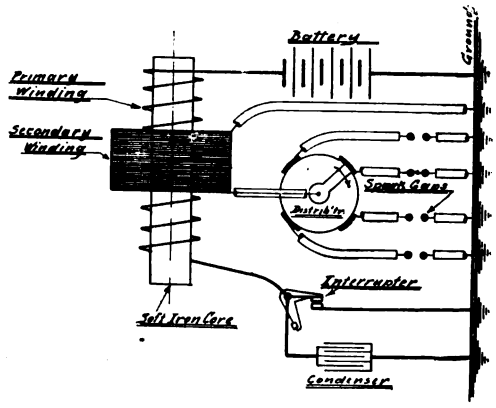

Fig. 1
Battery System.

the motor truck line, four-cylinder engines of four and a quarter inches bore, and six-cylinder engines of three and seven-eighths bore and under.

Modern motor characteristics in fact tend strongly to accentuate rather than to diminish the need for the true high-tension magneto, in reference to any form of the transformer or step-up systems.

Though such starting on the magneto alone by hand-cranking is therefore rendered easy at all times on practically all but the very largest of modern cars, by virtue of the present small-bore trend of engine design and by the adoption of sufficiently high capacity magnetos, the fact that few cars are nowadays produced without an electric motor for starting purposes renders such hand-cranking a practically obsolete performance.

The electric motors provided for starting purposes are as a rule able to spin four-cylinder engines at 150 or more revolutions per minute, and six-cylinders at 110 or more R.P.M. which rotative speeds with four-cylinder engines, on which the magnetos run at crankshaft speed only and with six-cylinder engines on which the magnetos run at one and one-half times crankshaft speed are sufficient to cause the magneto in slightly advanced position to generate an efficient spark for starting on full compression, after which there is no likelihood of experiencing any difficulty, as few automobile engines, once started, can continue to operate

Digitized by Google

on their own power at less than 170 revolutions per minute, an efficient magneto speed under heavy throttle conditions.

Owing to the lower resistance of the spark plug gap, sparking conditions are materially aided when starting the motor and when operating at very low speed, as the rarified condition of the throttled charge produces a very low compression pressure for the time being, and the comparatively low voltage magneto current secured at starting speeds is therefore ample to break down the comparatively slight resistance of the spark plug gap.

In practically all motors on which "Independent" magnetos (those not equipped for battery starting) are installed, an advance of from twelve to fifteen degrees or more before upper dead-center when cranking will not cause a back kick at any time for the reason that in order to cause an independent magneto to generate a spark strong enough to ignite the charge, the engine must be turned over at such a speed as will insure the engine's being carried over center against the early spark by reason of the energy stored up in the flywheel at that speed.

In view of the above mentioned circumstances it may readily be understood that the best modern magneto practice prescribes a vastly simpler and less costly ignition equipment than was common two or three years ago.

Though modern motor characteristics have made possible a simpler ignition equipment than that advised three or four years ago, it should by no means be assumed that the true high-tension magneto itself may advisedly be dispensed with in favor of any form of transformer or step-up ignition system, for the reason mainly, that the true high-tension magneto possesses certain qualities affecting efficiency and absolute reliability which cannot possibly be given to the transformer or step-up systems, for constructional reasons.

Battery Systems.

The more common types of battery ignition systems comprise: A timer-distributor, positively driven in a proper relation to the engine crankshaft; a stationary transformer coil containing a soft iron core, a primary winding of relatively few coils of comparatively large diameter copper wire, a secondary winding having thousands of turns of extremely small diameter copper wire; also a condenser made up of many alternate layers of tinfoil and thin insulating material such as mica or waxed paper. (See Fig. 1.)

The battery current usually passes first to ground, then through the "timer," then through the coil primary winding, and back to the battery; the timer cam being of such a length as to permit the battery current to flow long enough to highly magnetize the soft iron core of the coil through the electro-magnetic effect of the primary winding, and the timer (or interrupter) breaking the battery current at the instant when ignition of the cylinder charge is desired; the more rapid the break, the higher the efficiency of the transformer coil as a whole.

The magnetic flux generated in the iron core flows through and between the many turns of fine wire comprising the secondary winding. When the primary (battery) current is interrupted, the magnetic lines of force drop in strength, from maximum to practically zero, and with exceeding rapidity, such drop setting up in the secondary winding an extremely high-voltage, low-amperage current which is passed through a heavily insulated cable to the "distributor," this commutating the high-tension current to the cylinders in the proper rotation.

The condenser serves to take the "kick" of the primary winding when the battery current is interrupted, thus serving directly to prevent excessive sparking at the interrupter platinum points. The magnetic strength of the iron core, and therefore the output of the secondary coil depends, in part, upon the length of time in which the primary current acts; therefore, at high speeds the battery-transformer secondary current is by no means as strong as at low engine speeds.

Combined Battery and Dynamo.

In many of the combined starting, lighting and ignition outfits, the timer-distributor is located on the end of the lighting-and-charging dynamo shaft, or is gear-driven from the same, and arrangements

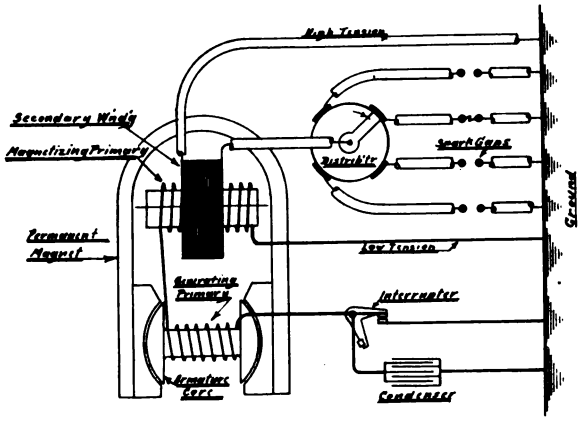

Fig. 2
Step-Up Magneto.

are made to pass automatically or at will, either battery or dynamo current into the stationary transformer-coil primary-winding. In all other particulars such equipment is exactly similar to the above described battery systems.

Transformer Magnetos.

High tension transformer-magnetos are made in many forms, but all of these comprise substantially all of the above described parts, functioning exactly as already indicated, with the exception that, when the engine is running on the magneto, the primary current is not furnished by a battery but is generated in the primary winding, through the action of a soft iron core fashioned into an armature core and rotating between the poles of one or more permanent magnets.

In some forms of transformer magnetos, a "generating-primary" winding is mounted upon the rotating armature core; the secondary winding in such instances being wound over a second primary winding on the soft iron core of a stationary transformer coil. (See Fig. 2.)

In various other forms of transformer magnetos, a single primary winding only, on the stationary transformer coil, is used, the magnetic flux from the

Digitized by Google

permanent magnets passing to the central soft iron core of the coil itself through a plain unwound, rotating armature core, which passes the flux on in turn through variously constructed stationary coil core extensions; the transformer or step-up coil being usually located just under the arch of the permanent magnets. (See Fig. 3.)

The transformer or step-up magneto and the combined dynamo-transformer are of course somewhat more preferable to the battery system, as the former types constitute practically inexhaustable sources of current, and as the secondary current from the "step-up" magneto increases rather than diminishes in strength as the engine speed rises.

It may readily be seen, however, that all of the above described outfits comprise nothing more or less than "step-up" ignition systems, and possess substantially the same characteristics as regards the nature of the high tension current produced.

True High-Tension Magneto.

The true high-tension magneto consists preferably of a laminated, soft iron, shuttle-armature core, rotating between the poles of one or more "U" shaped permanent magnets, this armature having wound upon it both the primary and the necessary windings, the secondary forming an extension of the primary, the inner end of the primary being grounded on the armature core, and the outer end of the secondary being led to the brass segment of a "slip ring" mounted upon the armature shaft, and turning with it.

The outer end of the primary besides being joined on to the inner end of the secondary, is also in electrical communication with the insulated side of the mechanically operated interrupter, also to one side of the condenser, the other side of the condenser being grounded to the armature core and to the magneto base. (See Fig. 4.)

The greatest difference in the electrical output of the "true high-tension" magneto and of those of the "step-up" type, is that more than a mere static flow to the spark plugs in the engine cylinders is obtained from the former instrument.

What is termed a "dynamic" flow is generated in the secondary winding by reason of the action of that winding in rotating through the permanent magnet field, this causing a further generation of current (exactly as in a dynamo) which flow is of somewhat lower voltage, but of considerably higher amperage than the static flow.

Though the dynamic flow is not of sufficient voltage to break down of itself the resistance of the spark plug gap, (excepting perhaps at the very high speeds sometimes attained in aero-motors), once the resistance of the gap under compression is broken down by the static discharge, the dynamic flow following immediately after meets with little resistance and also flows across. As the heat of the spark depends upon the amperage passed, that part of the spark caused by the high amperage "dynamic" flow is several times hotter than the spark resulting from a "static" discharge only, and the higher the rotative speed the more powerful the spark, a condition opposite that found in battery equipment.

Electrical Characteristics.

No standard spark plug gap can possibly be prescribed for all automobile engines, as the peculiarities due to differences of compression, location of spark plug, rotative speed, class of ignition accessory used, etc., would render advisable slight differences in that gap in nearly every make of engine.

For average conditions, however, a gap of approximately three-quarters of a millimeter (or about one thirty-second inch) will give good all around results.

The resistance of a gap of three-quarters of a millimeter under about seventy-five pounds compression is about equal to the resistance of an atmospheric gap of from five to six millimeters, depending upon atmospheric conditions.

If a static discharge such as is produced by all types of "step-up" or "transformer" ignition systems be passed across an atmospheric gap of five or six millimeters, an extremely thin white spark only is produced, as in Fig. 5. Should this spark be blown against by a current of air it will bend slightly, but its general appearance will not be changed, as Fig. 6 indicates.

Should the combined static and dynamic discharges of a true high-tension magneto be passed across the same gap, a very different spark is produced, as shown in Fig. 7. In this may be noticed a thin white core, representing the static spark, but this is surrounded by what is termed a "corona," or flame, of great diameter in the middle, decreasing

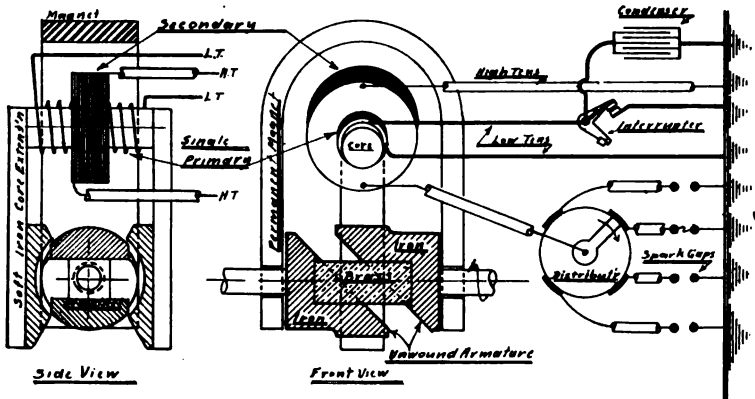

Fig. 3
Step-Up Magneto.

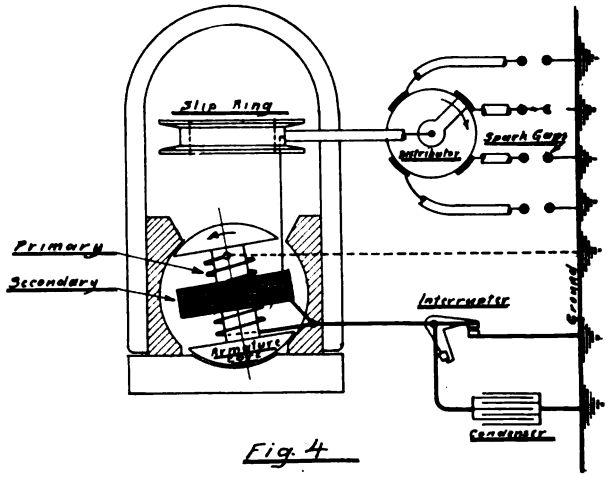

Fig. 4
True-High-Tension Magneto

Digitized by Google

to points at the gap terminals. Should this be blown against by a current of air a veritable flag of flame of considerable volume is produced, as in Fig. 8.

The same results are obtained at the terminals of a spark plug gap under compression; and it may readily be seen that the corona type spark will at all times be vastly more voluminous, as well as more productive of heat, than any mere static type spark could be, and at the instant of ignition will ignite a greater number of gas particles than a static spark can ignite. With a greater number of gas particles ignited to start with, a "true high-tension" magneto spark will assure an appreciably more rapid rate of flame propagation in the engine cylinder.

As a result, when compared to engines on which either battery-transformer or "step-up" magnetos are installed, the engine equipped with a true high-tension magneto will necessarily prove to be "snappier," more responsive in traffic, will not require as great a degree of advance under load, will not overheat as easily, and will require less fuel for a definite power output. In traffic or on rough or hilly ground where the rotative speed is liable to great and rapid changes from high to low and vice versa, the carburetor is constantly being more or less upset, giving alternately too rich or too poor a charge, a true high-tension magneto will continue to regularly fire such fluctuating charges when these are absolutely non-ignitable with only the static type spark of the transformer ignition system applied, and the static spark will often missfire even though it is occurring at the spark plug gap with utmost regularity.

Lag.

All battery and dynamo-transformer ignition equipment is subject to a decided "lag" between the

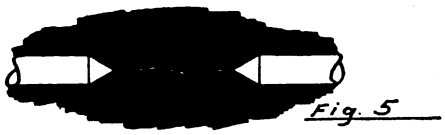

Fig. 5

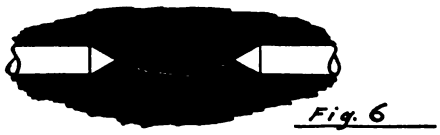

Fig. 6

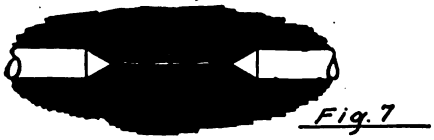

Fig. 7

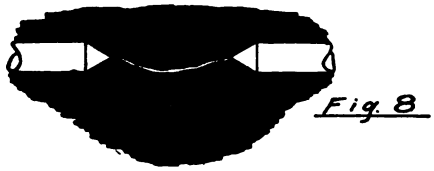

Fig. 8

interruption of the primary current and the occurrence of the static discharge at the plug gap, this lag retarding the spark in the cylinder, and to a much greater extent at high engine speeds than at low, just contrary to what would actually be required.

In some instances this difference of lag at high and low speed in battery and dynamo-transformer systems is found to amount to as much as 12° to 14° when the engine speed is varied from about 300 to 1,800 r.p.m., the timing lever position not being altered meanwhile.

With a true high-tension magneto no lag whatever is possible under any conditions, and with the spark set for a definite degree of advance, that advance will remain the same no matter whether the engine speed is greatly increased or diminished.

Some natural results are that the battery equipped engine, particularly if of the high-speed automobile-type, is by no means as responsive nor as certain in its action, is far more liable to overheating, is not as powerful, is more wasteful of fuel, and requires a great deal more manipulation of the spark-advance lever than is true in a similar engine equipped with a true high-tension magneto.

STORAGE BATTERIES.

Their Construction, Care, Recharging and Why They Often Become Exhausted.

From J. N. Bagley, Nebraska.—Storage batteries have been in use for some time, but many repairmen do not have the slightest idea how they are constructed or how to care for them. A storage battery properly cared for will give good results in nearly every case, and the use of them at the present time is growing so rapidly that it behooves every repairman to get acquainted with them so that he can give them the necessary care when they are left in his care in winter or when they are in constant use. A storage battery will require the same careful attention when not in use that it does when in daily service. In fact possibly more, as when they are in service and supplied with current and with a good generator, about all that is necessary is to keep the connections clean and tight and the liquid at the proper height above the plates. Storage batteries are constructed different ways, but the plan I have laid down in the drawings will make the inside construction plain, as the lines will not vary to any great extent.

We have in Fig. 1, at A, a common form of zinc construction found in the ordinary starting and lighting battery. The zinc plates are made up of thin slabs of zinc A, connected with a continuation of the same metal as shown at D. Then at E, we have a neck of zinc into which a knurled lead screw, F, is screwed to secure the connecting wire to the next part of the battery or to some other part of the machine. On either side of A is a separator B, C, to protect the zincs from coming in contact with each other and causing what is known as a "short." When a battery "shorts" the charge of stored electricity will leak out the same as water would leak out of a bucket if it were pierced with some sharp instrument. The insulating separators are installed as shown at C, across the entire construction. If we place into the spaces another zinc construction we will have the two connected as would two combs if the teeth of each were forced together except that the teeth would be insulated from each other.

In Fig. 2 we have the assembled construction set into a suitable receptacle, generally made of a hard rubber substance or some composition that will not

Digitized by Google

be affected by the acid when it is placed inside and around the plates. In the bottom of the reservoir we have at A, a small projection extending an inch above the bottom and holding the zinc construction up from the bottom. The space B acts as a catch for all sediment and scale that will come off the plates, as the battery grows older, and if this allowance were not made the sediment would short the plates and the battery would be worthless until

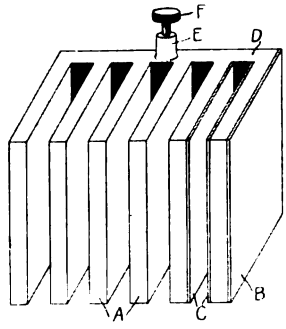

Fig. 1

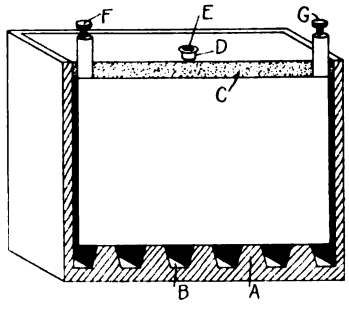

Fig. 2.

it was removed as it would cause a "short" and the battery would lose its charge. Now that the zinc construction is placed and sealed as at C, over the top, we are ready to place the solution of sulphuric acid. The strength of the solution will vary, depending on the battery construction. Before placing the solution, the instructions of the battery manufacturer should be followed very closely. In case the mixture should be too strong it would have a tendency to cause an excessive scale of the plates should not be put in until the plates are entirely covered and should be kept at this level at all times. The filling neck, D, has a small vent hole, E, which should be kept open. The terminals F and G will be the positive and negative poles of the battery and will be known as negative and positive. These should not be confused as on them depend much in charging or repairing the battery.

In Fig. 3 at A, B, C, we have the three cells ready to place in the container which is usually made of

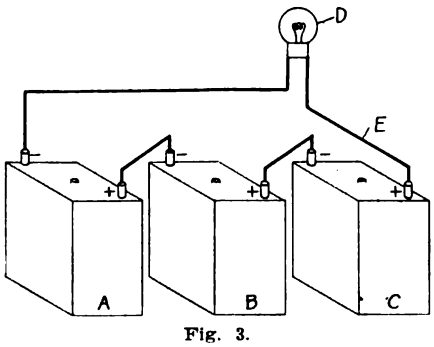

Fig. 3.

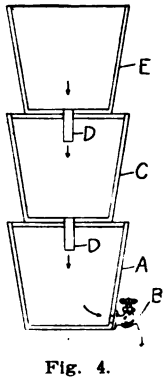

Fig. 4.

soft wood supplied with a couple of handles. After being placed the cells may be united with a sort of wax over and around the top and between the cells, as this prevents their working together or being cracked. The ordinary battery used about the car for starting and lighting is usually a 6 or 7 volt. We will take a six for example, as shown, A, B, C, are 3 cells of 2 volts each connected to give a continuous current to the small incandescent globe D. Now if we place the wire E on the positive post in cell A, we get a dim light with two volts which will have a certain amperage output for a given time. If we take wire E, and place it at positive on cell B, we will have an increased voltage pressure to 4 volts; consequently the size of the lamp can be increased in voltage with the same amperage. Now if we place wire E on the positive of unit C, we have the three cells in series and have increased the voltage to 6 volts, giving still a higher rate of output, as will be better understood by the buckets of water shown in Fig. 4. We have at A a two-gallon bucket of water with a spigot B, which will regulate the discharge of the pail. We will regulate it so that by the time the bucket is empty the first cell A, of two volts, will be discharged. Then we will add another pail C, above with an opening D, into the lower pail A, and this will compare with the second cell B, in Fig. 3. We then add the third pail of water as shown at E, with and opening D, into pail C, making the three in series as in Fig. 3. We thus have 6 gallons of water to discharge through the same opening, which gives a higher pressure with a given output. If the size of the opening B, be larger, the rate of hours in output will be lessened accordingly, and the same will be in case the larger globes are used on the three cells in Fig. 3. We can place globes

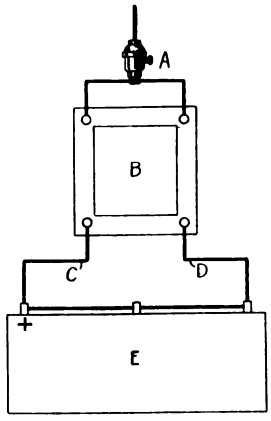

Fig. 5.

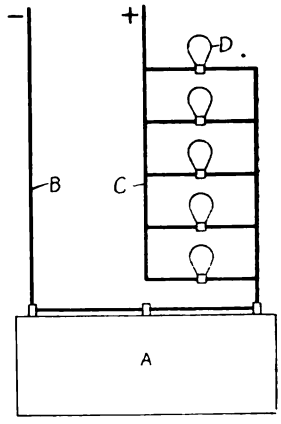

Fig. 6.

to use the current in a very short time or we can place the large spigot to allow the water to flow in the same length of time. After the discharge it will be necessary to charge the battery from an outside source before it will give further service. The pails must also be filled with water again before they have an output. To make plain, this point of recharge will be illustrated in the drawing in Fig. 5. We have at A a common lamp socket in an alternating current. This current cannot be used for charging, as the direct current is required to charge the storage battery, consequently it is necessary to use a rectifier to change the current back, to direct it before reaching the battery. To do this we use what is shown at B, with wires C and D. Place the stripped ends of the wires in a weak solution of sulphuric acid and water and note which of the wires gives off a fine spray of bubbles. This wire is known as the negative and should be attached to the terminal on battery, marked —. The other wire, being the positive and marked +, should be made secure to the post marked so. E represents the complete battery connected to the rectifier for a charge, and the time for the recharge will depend on the make and style of the battery, which will be given by the maker and is usually printed and placed somewhere about the battery.

At A, Fig. 6, we have a battery being charged

Digitized by Google

direct from a direct current generator of 110 volts. Now we will take the two wires leading from the generator B and C, and find which is the negative and place it in position. The positive wire will take into its line, as shown at D, a series of incandescent lamps to regulate the amperage before entering the battery. The charging rate will be found stamped on the battery and this should be consulted before making the charge, as it should not be charged other than the rate recommended by the maker.

To tell when the battery had its proper charge, a device known as a hydrometer is used and the same is shown in Fig. 7. It consists of a glass tube A. On one end is a rubber bulb B. Inside the glass tube A, is placed another little tube C, correctly weighted with small shot D, and graduated as at E, to tell the specific gravity of the liquid in the battery. Now by squeezing the bulb tightly and placing the rubber tube F, into the liquid and releasing it, the liquid will be drawn into the tube A, around the inner tube C, floating it, when the density of the liquid over-balances the weight of the inner tube. At the time the inner tube floats, the liquid will hold a line somewhere along the graduated portion E, of the tube C. When the line at which it floats corresponds with the figures on the tube C, the specific gravity will be registered.

At specific gravity 1,120, the battery is practically discharged and will freeze at 20 degrees above zero.

At specific gravity of 1,160, the battery is three-quarters discharged and will freeze at around zero.

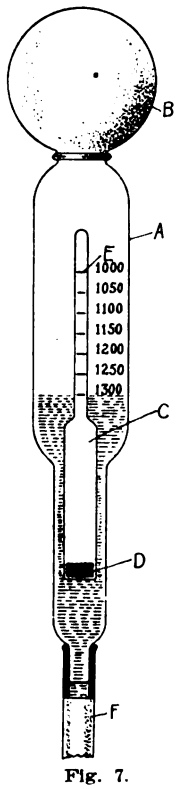

Fig. 7.

At specific gravity 1,210, the battery is one-half discharged and will freeze at about 20 degrees below zero.

At specific gravity of 1,260, the battery is one-fourth discharged and will freeze at 60 degrees below zero.

At specific gravity of 1,300, the battery is considered fully charged and will not freeze in any weather which the battery is subjected to under ordinary conditions.

Many times the battery A, Fig. 3, will show a defect when it looks all right so far as outside appearance is concerned. An internal trouble can be located with a small lamp, B, and a couple of wires, C, D, as shown in Fig. 8. By placing the wires shown in the drawing we will get connection to the one single cell, and if the lamp burns, move the wires over to E and F, and note the condition of it

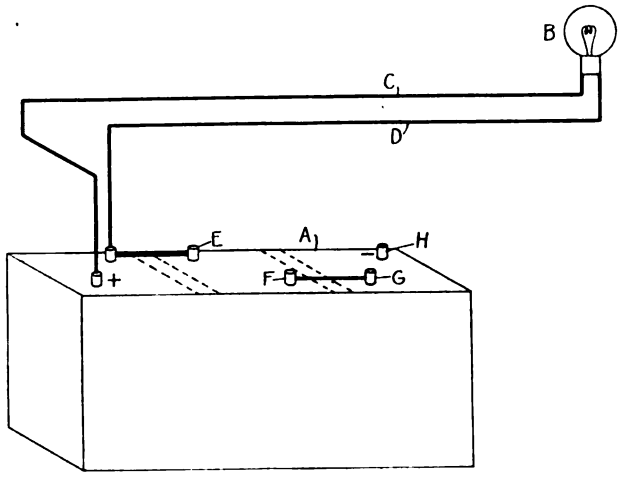

Fig. 8.

as compared to the previous one. If all are the same, move the wires to G and H, and test as before, and if it shows a weakness the trouble is with the last cell tested. If all the cells show a uniform and even light by the means of the lamp, it indicates that the battery A, is in a discharged condition and should be charged at once.

There is a great danger in leaving a battery in a discharged condition for a long period, or if the plates are not entirely covered with the solution, the elements will become sulphated and the capacity greatly reduced. Many times the sulphate can be removed by a prolonged charge at a very low rate, but more frequently destruction of a cell or the entire battery is the result of such neglect and it is best to not run the dangerous chances with the battery.

There are specific causes of battery exhaustion or a partial exhaustion and they can be noticed by the following symptoms, unless some exceptional circumstances are encountered. The lamps will burn brightly for an instant and will sink to a dim red light and remain so, or the starting motor will refuse to turn the engine over. In this case the switch should not be closed, for when the battery is in a discharged condition a slight drain only adds danger of ruin. The starting motor which engaged with the switch separately from the motor will move too slow.

There are a number of battery exhaustion causes which can be laid down as a rule and not as exceptions, and we might mention the following as some of the most common: The dynamo not charging, which might result from a number of causes, such as broken or dirty brushes, open circuit, fuses blown and many other things. The wires may be short circuited or broken, or there may be a short circuit in the battery, which can be found with the test lamp as already described. Drain on the battery by an excessive load which might result from a car standing a great deal on the street after night

Digitized by Google

and very little running. The dynamo belt may be slipping in case a belt is used. The clutch may be slipping or the connecting device between the dynamo and driving device from the engine may be broken. An excessive amount of oil placed in the bearings may find its way to the brushed bearing on the commutator and prevent a generation of current, in which case the battery would discharge quite rapidly as no outside source would counterbalance the discharge.

When the car is stored and the battery is not going to be put to service for any length of time, it is a very good plan to disconnect the wires. In case there is a partial short in the wiring, the battery would not suffer for it. The battery should receive a partial if not a whole charge at least once a month when not in use. In case the battery is left in the car and is charged by a small generator driven by the motor, the engine can be started and run a short time at intervals and in so doing the battery will be kept in very good condition; but aside from this, distilled water should be added to keep the plates covered for if they are left uncovered the result will be as already described.

If serious battery trouble develops that cannot be overcome by ordinary treatment it is better to either return the battery to the makers, or at least take the matter up with them, explaining all the details and they will at once advise what to do. A battery should never be torn up by one not entirely competent to handle and make the necessary repair. Never use the ammeter on the battery that is used for testing the ordinary dry cells or there will be use for an additional order for the order book, and there will be a flash inside and a smoke will appear under the dial, and the story is told.

CLUTCH MECHANISMS.

More Points Upon a Most Important Feature of Automobile Construction.

Next to the ignition, the clutch of an automobile gives more trouble than any other part of the car. This is due to the fact that the principle of friction as a locking device is by no means mechanically perfect. Unless used with the rarest skill and judgment, it is bound to get out of order, and when not in good condition it is liable to injure the car. If it is fierce, it is impossible to take up the drive gradually, and great strain is caused to the engine, gear, transmission system and tires. The care of the clutch is an essential factor of good driving. In starting, the clutch should be brought into operation so gradually that the car moves off without the slightest jerk. In gear changing, the clutch action should be sympathetic and should synchronize with the gear-changing effort. There should be no undue hesitation in letting the clutch into operation again, but at the same time this should be effected so that there is no jerk in taking up the drive. In changing up, especially, this is important. If the change is very rapid when changing down, the clutch can as a rule be let right home, for the pace of the car will not be dropped below the speed represented by the gear on to which the driver has dropped. If, however, the driver is unskillful and changes slowly, or if the gears are badly designed or constructed and do not therefore change at once, it is essential that the clutch should let slip slightly so as to take up the drive gradually, otherwise there will be an injurious jerk. On the other hand, if the clutch is slipped too much the car may continue to slow down—in extreme cases to such an extent that the engine will not be able to take the gear without laboring unduly—which may necessitate dropping on to a still lower gear. Also, if the clutch is withdrawn in traffic, so that the pace slows, it should be let in again very gradually. Of if the car is running free downhill, and has attained a greater pace than corresponds with the speed of the particular gear which happened to be in mesh, the same precaution should be observed.

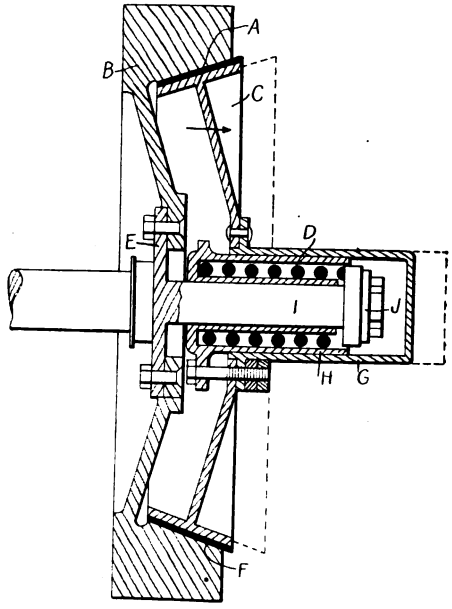

Fig. 1.—Cone Clutch.

Clutch slipping, of course, causes a certain amount of wear on the clutch faces, and consequently should not be unduly resorted to, as when checking the pace in traffic or nursing the car over the crest of a hill in order to avoid the necessity of changing gear. Generally speaking, it is better to change under such circumstances. Properly constructed plate or disk clutches, working in oil, can be slipped to a greater extent without undue wear than cone or expanding clutches. In fact, in the case of some plate-clutches drivers report that they have found it possible by slipping the clutch to run at such a crawling pace on the high gear as would otherwise be impossible without causing the engine to labor, and nevertheless, after a whole season's use, the wear was hardly appreciable.

The multiple disc and the cone clutches are the ones in common use, and there are several forms of each, some of which will be found illustrated and described herewith.

The cone clutch is simple in construction as clutches go, and easily understood. It has but few parts, and there is little liability of its giving any trouble, if used properly and the surface is kept in proper condition. In Figs. 1, 2 and 3 there are shown three types of the cone clutch. These are illustrated to show and make clear to the motorist some important points in the construction of cone

Digitized by Google

clutches, and as they are sectional views, one can easily study their operation and the way they are put together. In Fig. 1, we have a cone clutch having a part A, formed integral with the fly wheel B, a corresponding member C, which fits into it. It has a spring D, to give contact between the surfaces. The fly wheel is fastened to a flange E, on the end of the crank shaft. The member C, is of metal, and is faced with leather as shown at F. The part C, is carried by a hub G, which in turn fits over the part H, which bears on the crank shaft extension I. The spring D, presses on the closed end of the part H, and is held by a nut J, on the end of the crank shaft extension. The spring pressure in this case keeps the cone C, seated by pushing it towards the crank shaft. When it is desired to release the clutch, the pedal is operated in such a manner that it moves the cone C, and the part H, away from the fly wheel, and the spring is compressed. Fig. 2 is a cone clutch with its part A, being a separate casting bolted to the fly wheel rim B, which differs from Fig. 1. To operate the cone member C, away from its seat in part A, it travels in the direction of the arrow. In Fig. 1, it is operated in the reverse as shown by the arrow. In Fig. 3 is shown a cone clutch which has friction shoes A, to grip the fly wheel B, before the cone C, is fully engaged, to secure gradual application of power.

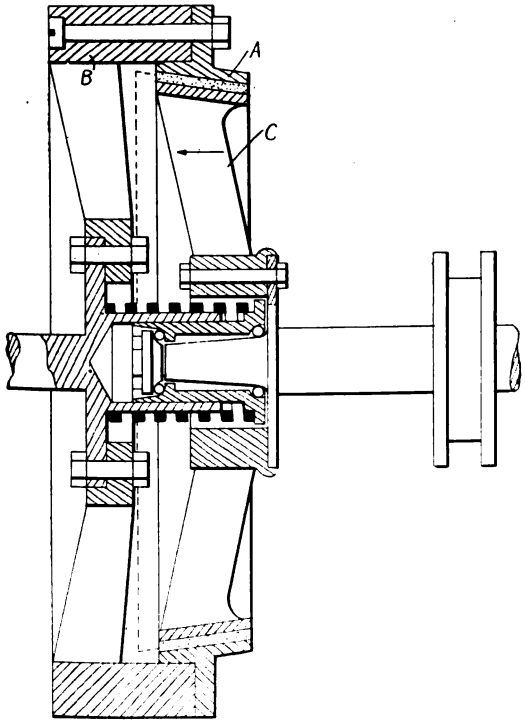

Fig. 2.—Cone Clutch.

There are eight friction shoes used, and spaced as shown in the diagram D. Each shoe extends through an opening in the cone C, and projects slightly above its surface. These shoes are held in place by a spring F. When the clutch is first engaged, the shoes engage the part B, and then when full spring pressure is exerted, it overcomes the resistance of the springs F. When this takes place the shoes will be flush with the surface of the cone member C, which will then take the drive.

A type of multiple disc clutch that is widely employed, consists of a number of soft steel discs which alternate with others of different material as shown at Fig. 4. One set of these discs is carried by a driving drum while the other plates are attached to the fly wheel. Usually the pressure is

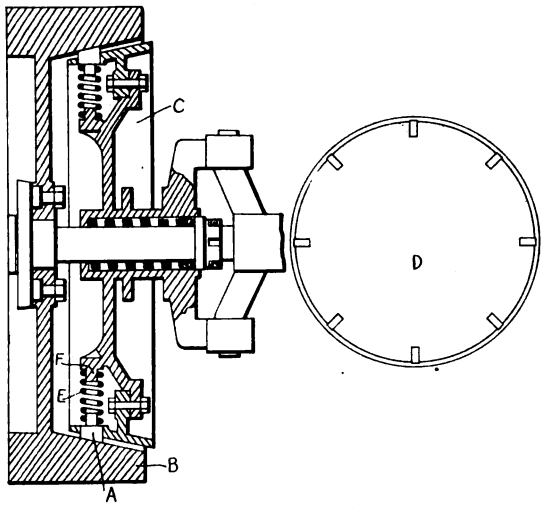

Fig. 3.—Cone Clutch.

obtained by a coil spring. While a multiple disc clutch does not have a tendency to spin, the plates may sometimes refuse to disengage because of a partial vacuum existing between them. This trouble is seldom present unless poor lubricating oil is used between the plates. In the illustration, the clutch case is cast integral with the fly wheel and forms the fly wheel hub. The series of discs marked A, are carried by the driving drum B, and are kept in engagement with those carried by the fly wheel C, by means of pressure derived from the spring D, which is let into a bored out recess at the end of the crank shaft G. The clutch shown is intended to run in oil and a number of the plates are provided with cork inserts. Oftentimes it is necessary to examine the parts marked E, F, as well as the discs A, spring D, etc., for without them the clutch will not work as it ought to and will often be found to be the whole cause of many clutch troubles. The form of clutch shown is in use on Hudson cars, and is simple in construction and operation.

If, when changing speed, the gear misses, depress the clutch pedal again quickly, and the gears will invariably come in at once without causing any jar upon them. When firmly in, the clutch should be let in gently to pick up the momentum that car has lost.

Sometimes when a gear change from a lower to a higher speed has been made, it will be found that the engine commences to thump heavily. This is due to the fact that the change has been made a little too soon and before the speed of the car or the resistance warranted it. The thumping can be instantly stopped by lightly touching the clutch pedal, so that a little slip takes place. The engine then quickly picks up, and the thumping ceases.

Owners of cars with epicycloidal change speed gearing should be particularly careful to change

Digitized by Google

their gears gently. As a matter of fact, the amateur driver who is used to sliding gear changing is, for a short time, hopelessly at sea on a car with the type of gear mentioned, for whereas with the sliding gear a quick motion is necessary for gear changing, the other type requires a gradual feeling action for the change. Thus on cars employing epicylic gears, the driver should be careful to apply the brake which changes the gear as gradually as possible, and otherwise the strain on the gear is very considerable, and stripping a by no means distant possibility. Lubrication of the drums is quite permissible, and is usually provided for, but if not, the driver of the car should see that some thin oil is used occasionally to grease the peripheries of the various speed-changing brake drums.

When one has run up to and come to a rest at a point at which it is desired to stop on top speed, a

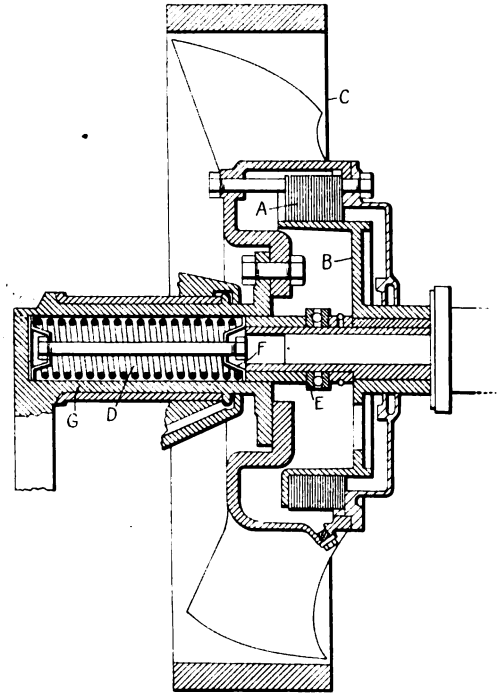

Fig. 4.—Multiple Disc Clutch Assembly.

little difficulty will sometimes be found in returning the change speed lever to the neutral notch in the quadrant. The teeth of the toothed wheels on the sliding sleeve on the clutchshaft do not at the moment exactly coincide with the gaps in the toothed wheels on the gearshaft, and the wheels will not pass each other. Of course, the clutch can be let in slightly, which would alter their position with regard to each other, but not infrequently the teeth still foul. The depression of the brake pedal, however, and consequent grip of the brake bands, or blocks, on the brake drum will, permitted by the slight play in the propeller-shaft, cause the gearshaft to move just enough to permit the passage of the wheels on the sliding sleeve through their fellows, and allow the neutral notch to be at once attained.

This can be done in the garage or anywhere private. Block up the rear axle well and solidly, so that the tires are at least two inches from the ground level, and wedge the front wheels at front and back, with substanial wedges or planks. Start up the engine again, and sit at the steering wheel seat; depress the clutch pedal slightly, and gently work the speed lever to try and bring it into the first speed notch. Probably a grating noise will be heard, and you may fail to get the wheels properly in mesh. Let back the lever to its original position and try again. If the lever goes into the notch, then at once let up the clutch pedal gently, and you will notice the rear wheels will at once commence to revolve. Depress the clutch and they will stop; let it in again and they start. Practice this, and afterward try to get in the next speed higher, first by depressing the clutch, and at the same instant bring the speed lever into the next higher notch, and immediately let the clutch in gently without loss of time. The rear wheels will now revolve faster, and you can then try higher speeds; then practice reducing the gear by doing everything in the same order. While on each of the gears, the engine can be run fast or slow with the throttle and spark levers, as before mentioned. The reverse can then be tried exactly in the same manner, most cars having the reverse and forward speeds actuated by means of one lever. In the exceptions to this rule there is no difficulty in following out the operations to be gone through if the levers are carefully examined and their effect noted when they are operated.

Care of Springs.

Few motorists take the trouble properly to guard the welfare of the springs on their cars. It is, however, a fact that if they do not receive attention occasionally they will not perform their work in anything like the efficient manner that they would otherwise do. The leaves should be oiled every now and then, and about once a year the springs should be taken down and each leaf painted either with graphite or white lead. The coating must not be too thick, but if the springs are properly treated in this way they will not tend to rust, and squeaking will not be apparent; the springs will also perform their work in a much more efficient way if they are properly cared for.

All the steering joints should be properly lubricated, and one should always make a point of testing the steering wheel alignment every month or two so as to ensure that the wheels are not out of track. If they are, considerable extra strain is thrown on the steering gear, and the tires will wear out far more quickly than they would do when running under proper conditions.

Cars in which electrical starting mechanism and a lighting outfit are installed impose extra duty on the driver, and that is the occasional inspection of the wiring to see that there are no loose contacts at terminals or damaged places in the insulation.

Few persons ever think of the ball bearings until some mechanic calls their attention to the injury done by breakage. At least once in six months ball bearings should be inspected, the rough or worn balls replaced with perfect ones, and the ball run filled with graphite grease.

If you will use soft yarn instead of hard-woven thread in mending tears in leather or mohair cloth, the stitches will not tear out quickly.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1574 Misses at High Speed and High Gear.

From M. R. Chappell, Colorado.—I own a Studebaker car, 1912 model, 30 horsepower. I am having some trouble with it on account of it missing or choking when in high gear at high speed, or on a hard pull, or rather a long, steady pull on a hill or steep grade. Also when on the level and I go to speeding up to 20 to 25 miles an hour it will go to missing. I open up the throttle to make it pick up and it will choke or go to missing. I have had new platinum points put in; had the magneto examined and also had the coil examined. Am at a loss to know the cause of this.

Reply.—The fact that your trouble seems to occur only at high engine speed would seem to indicate that the trouble is more likely in the carburetion than ignition, for missing of explosions noted at slow engine speed usually disappears at high speed. It looks to us very much as though you do not preheat the air which is used to atomize the gasoline, the result being that liquid gasoline accumulates in the inlet manifold and valve chests until the mixture becomes too rich. It may be that your carburetor is one of the earlier models without a hot water jacket. In using to-day's heavy gasoline it becomes practically always necessary to use heat to completely atomize it. We think you may find it expedient to use a more modern model of carburetor than the one with which the car was equipped three years ago. There is a possibility, of course, that the exhaust valve springs may be a little weak, rendering their action a trifle sluggish and permitting burned gas to be drawn in with the explosive mixture at high speed. Weak inlet valve springs would reveal themselves by blowing gas back through the carburetor.

1575 Metz Car Troubles.

From W. E. T., Maryland.—1—In a Metz car, 1914 model, with Bosch magneto, and a carburetor bearing the stamp of the Waltham Tool Co., cylinders No. 3 and 4 will fire when the motor is first started, but Nos. 1 and 2 will not fire until the motor is raced, and will stop as soon as the motor slows down. After the motor becomes heated Nos. 1, 2 and 3 will fire pretty well at medium or high speed, and 4 will fire about half the time. All four will fire sometimes on a hard pull until the motor slows down. With a rich mixture Nos. 1 and 2 will sometimes fire on starting. On a lean mixture No. 4 will fire after the motor is warm, but no mixture can be found that will fire all four. The valves have been ground and carbon cleaned out of the cylinder. No. 4 was rather dirty but it was soft. 2.—can you tell me what to do with the Metz friction drive to prevent its slipping. Out of four of these cars here not one clutch can be adjusted so that the drive will start the car up on ordinary grade or out of a "gulf."

Reply.—1—Your trouble is undoubtedly caused by either worn inlet valve stem bushings, poorly fitting piston and rings, or a combination of the two There is little doubt that the piston and rings in the No. 4 cylinder do not fit as they should, judging from the soft carbon accumulation. We do not know this carburetor. Some take a higher vacuum than others to properly vaporize the gasoline, and in such cases they are more susceptible to slight air leaks past the inlet valve stems which do not materially affect a motor's running except the throttle is nearly closed, as when running idle. 2.—A considerably heavier clutch spring might do it, provided it did not cause trouble somewhere else. You could hardly expect us to offer design changes to the manufacturer of a car.

1576 A Missing Cylinder.

From a Reader.—I have a Buick, model B 25, 1913, which has been giving lots of trouble lately. It all seems to be in the back cylinder and spark plug. After cleaning the spark plug it will go only three or four miles and then it misses badly. On removing it I find it very foul. The other three burn nice and clean. The back one sparks fine when first cleaned. I have had the piston taken out and holes drilled in it for the oil to go back through, but it is as bad as ever, worse if anything. The valves and rings are in good shape, the carbon burned out and spark plugs in good shape, and I have cleaned out and put new oil in the crankcase. They claim the wiring is also O. K. It costs a good sized garage bill for them to experiment, but the trouble is still there. There is also a knock in the engine on a hard pull, but they say it is not a carbon knock. Can you give me any suggestions in your next magazine? It has also been tightened up in the crankcase.

Reply.—We do not believe you will be able to remedy the trouble without fitting a new piston and rings to this rear cylinder, and you may find it necessary to have Nos. 3 and 4 cylinders reground and new pistons and rings fitted to both. There are several plants fitted to do this work, the usual charge for this being $10 per cylinder. Regrinding will be necessary if the rear cylinder is badly "scored" or much out of round. The knock may be what is known as a "piston knock."

1577 A Missing Metz Cylinder.

From Bennett S. White, New York.—I have a Metz car, model 1912, 22 H. P., with Bosch high-tension magneto. I have been having trouble and need help as I have tried everything I could think of without perfect results. I will give you the condition of the car and then the troubles. I have just cleaned the cylinder heads, tops of pistons, ground in the valves to good seats, etc. The spark plugs are clean and the porcelains are not cracked. I have had the spark gaps at all distances from .005 inch

Digitized by Google

under to .010 inch over 1/32 inch. The distributor brush of the magneto has been reversed, making it like new; the terminal contacts have been cleaned with emery cloth where blacked by arc from the distributor brush; screw No. 2 of the magneto is tight; interrupter parts are clean and freed of oil; platinum contacts meet squarely but are .005 inch further apart than the gauge furnished on the magneto wrench when the lever is resting on cam piece. The cables seem to be O. K.; the gasoline at 60 degrees temperature is 61 to 62 degrees Baume. I use Havoline light and medium oil as advised by the Metz Company. The oil level is only to the indicator cock in the crankcase. The cylinders have about an equal compression of about 25 pounds tangential pull on the crank handle. There is no air leak in the intake manifold; there are new gaskets on the same. In the three seasons of use the car has traveled only three thousand one hundred miles. The valve stems and bushings are only slightly worn, and the carburetor has been tried at all adjustments from ½ to 3 turns. The engine will run with all three cables disconnected from the plugs, but with all plugs connected up, the engine will stop if the two front plugs are short circuited by screw drivers. Short circuiting the two rear plugs in this manner has no effect on the running of the engine. If the front cables are disconnected from the plugs and are not allowed to touch any part of the motor, the two rear cylinders will not fire, but as soon as the front cables are allowed to touch the engine the two rear cylinders will fire. There is a halo around the third plug porcelain, if the engine is all connected up and throttled down. This is a new plug with sound porcelain. All plugs are the extra long Champion, made especially for Metz cars. The fourth or rear plug is always wet and sometimes dripping with oil. The first and third plugs are wholly wet or rather moist with oil but I have never seen any of the plug gaps closed by oil or soot deposit. Oil drips from the muffler occasionally. The exhaust is very smoky, especially when the engine is speeded. When driving the car at 15 miles per hour or more the missing is not noticeable, but when throttled down the car jerks and the engine pounds, due to the irregular firing of one or possibly both of the rear cylinders. When cleaning the engine I notice that there was some soot coating in the intake manifold; also down in the carburetor.

Reply.—Your entire trouble seems primarily due to poorly fitting pistons and rings, with the cylinders, especially Nos. 3 and 4, probably "scored" or worn worse than the front pair. The only remedy would be to have these two cylinders re-ground and fitted with new pistons and rings. Your abuse of the Bosch magneto could well be used by the Bosch Magneto Company as evidence of its strong design and sturdy construction. The use of emery cloth on the distributor plate was bad enough, but when you remove the plug cables and see that the bored ends do not touch any part of the motor, you were indeed taking desperate chances of ruining the secondary armature winding. Short-circuiting the plugs in the front pair of cylinders, resulting in stopping the motor, shows that the rear pair were not developing much power, not enough to compress the gas in the front cylinders, while short-circuiting the rear pair did not make much difference, as the compression, from your account, in these cylinders must be very poor. While a thin or medium oil may have been correct for the engine when new it is manifestly unsuitable now. While you are having the two rear cylinders reground and fitted with new pistons, our advice to you is to have all four attended to in order to get the same lubrication results in all four. The usual cost of this work is about $10 per cylinder.

The carbon deposits in the inlet manifold and carburetor are probably caused by "back fires," a result of too lean a mixture or improper seating of the inlet valves. If there is any leak of air past the inlet valve stems they should be rebushed. The reason the missing of explosions is more noticeable when throttled below fifteen miles per hour is because the throttling causes an increase of vacuum in the cylinders sufficient to draw oil past the ill fitting pistons and rings, and this soots the plugs causing missing of explosions. You must be using a lot of lubricating oil.

1578 Second Cylinder Misses.

From L. H. Bender, Michigan.—I have an Overland car and the second cylinder misses. That is the only one that does. I cannot feel any difference in the compression. It gets a good spark, the valves have been ground and I have changed spark plugs. It cannot be in the carburetor and be the same cylinder all the while can it? Can you help me?

Reply.—In relation to the missing cylinder of your Overland car, if you are sure it is not due to a defective spark plug or valve, then it is probably caused by a disconnected high-tension wire. This is assuming that the missing is regular and at every impulse of the motor. If it is an intermittent missing the cause is usually a loose terminal connection or it may be due to a valve that is not closing tightly.

1579 Certain Inquiries.

From C. E. P., Iowa.—I am a subscriber to your journal and read the Trouble Department with interest, as I am always willing to learn. Will you answer a few questions through your paper? 1—I have a new master vibrator put on my car. It is manufactured by the New York Coil Company. My car is a model T, Ford, 1913. When I hold the vibrator down lightly the car seems to run smoother and at night the lights will give more light as I use the magneto for light and ignition. It seems to me that the contact is too close. It vibrates all right, but what I want to know is—the motor may run idle all right, but if I contrive a washer on the back of the spring to hold it down a little (as it is the straight flat spring type 1914, I believe) when on a hard pull and the cylinder under full compression, would it throw a spark across the spark plug gap? The upper contact point can go no higher. Will a light contact damage the vibrator or wear the points more? 2—My car leaks considerable grease at the rear brake bands. My motor has been taking more lubrication oil than I think it should. I can hardly keep it at the right height. It will idle and consume very little. Is it possible that the lubrication oil, in going up-hill runs back through the drive shaft housing and thins the grease so it runs out at the ends of the axle housing? I think this is the case with many cars. Do you think it would be advisable to install a new Universal ball cap with a new bear-

Digitized by Google

ing, No. 3369, as listed in the price list of parts put out by the Ford Motor Company? If this is the case, it would make a tight bearing and keep the oil in the transmission case. 3—When a Holley carburetor leaks and overflows, how is it remedied? 4—How should the gasoline inlet needle be seated; should it be ground with fine valve grinding compound or would a new inlet needle be best?

Reply.—1—The closer the vibrator is adjusted the more current it will take. Your master vibrator should only be adjusted sufficiently close to prevent missing of explosions. Some careful drivers adjust closely for starting and then slack the adjusting screw a little after the engine gets warmed up. Closely adjusted vibrators use up battery current much more rapidly than if economically adjusted, and use up vibrator contacts more rapidly. 2—You may have diagnosed the case correctly. A new cup and bearing, while not expensive, would prove the correctness of your theory. 3—By renewing, or drying out and re-shellacing the float, or regrinding or resetting the needle valve. 4—Regrind with a little ground glass and heavy oil. Be careful not to revolve the valve completely on its seat. A screwdriver in the slotted head should turn the trick. A new valve would have to be ground to its seat.

1580 **Spark Plugs.**

From E. S. Richardson, Illinois.—I have a T head motor with 4 plugs over the intake valves, getting current from a Bosch magneto, type DU 4, model 5A duplex. Can I put 4 Pecco or Su-Dig spark plugs (as advertised in your magazine) over the exhaust valves, connect them up as directed, using my present magneto, and get as hot and efficient a spark on all 8 plugs as I am now getting on my present 4 plugs?

Reply.—The manufacturers of both the spark plugs named are in every way reliable and their claims are no doubt based upon substantial facts. If they tell you that their spark plugs will give as hot and efficient sparks on all 8 plugs as you are now getting on your 4 plugs, you may be sure that they have reason for their claims. We are inclined to think likewise that they are willing to guarantee whatever they state. We don't see how you can ask for anything more.

1581 **A Tight Fit.**

From B. R. Dixon, New Jersey.—I have just finished putting new rings in each piston and closed the bearings. Had my magneto (Splitdorf) overhauled and battery recharged. I cannot crank the engine with all of the spark plugs in and I think I will have to have the car towed before I can get the engine started. When I crank the engine with three plugs out, the gasoline spurts out of the breather tube of the carburetor, not constant, but once or twice for each revolution of the crank handle. My car is a 4 cylinder Buick, 1912. I also had the valves ground by a machinist. The carburetor was O. K. before I put the car away in July. My carburetor is a model L Schebler. I have asked several men who are well informed (or who claim to be) on the construction and operation of auto engines but this is a new one to them.

Reply.—You have probably fitted the rings too closely, leaving an insufficient space at the point of parting, or you may have fitted the bearings so closely that they grip the shaft. The blowing back through the carburetor is due to the inlet valves not seating properly, and may be a result of getting some of the grinding material into the inlet valve stem guides. What you style the "breather tube of the carburetor" is probably the auxiliary air opening.

1582 **Not Generally Known.**

From R. H. Dickson, Washington.—Kindly give me the following desired information: 1—What is the specific gravity of the gasoline in common use to-day? 2—What is the number of heat units per pound of the same gasoline? 3—About how many pounds below atmosphere is the pressure in the intake manifold of such cars as the Cadillac, Buick, Overland and Ford, with throttle wide open? 4—What is the compression pressure in the above mentioned cars? 5—Was it due to having double intake valves, thus giving easy ingress of the gas to the cylinders and thereby increasing the horsepower slightly, that the French cars were able to defeat the American cars last year at Indianapolis? 6—What is the rated horsepower of the starting motors on the cars mentioned in question 3 (except the Ford)?

Reply.—1—Probably from 56 degrees Beaumè, equivalent to a specific gravity of about .753 to 62 degrees Beaumè, correspondent to about .729, depending upon the crude from which the gasoline is distilled and the producer. There is a great variation in gravity, and producers will rarely guarantee any particular standard, except of course the 76-degree, which must show at least 74 degrees Beaumè, about .686 S. G. 2—Approximately 19,000 to 19,500 B. T. U. per pound. The lighter the fuel the less per gallon, consequently a gallon of heavy gasoline would contain more British thermal units than an equal quantity of lighter weight petroleum product. 3—Pressure below atmosphere is recorded in inches of mercury vacuum. Your query is indefinite in that the engine might be stopped, it might be racing, or the clutch might be let in on high gear on a hill, in each case setting up entirely different conditions. Even at that no one should presume to attempt to make reply except he had really made such useless experiments. 4—We have no means of knowing. 5—We do not know. It may have been that these drivers were more proficient, that they had less tire trouble or that they were just lucky. 6—We do not know. The manufacturers of the starting systems would possibly not tell you anything of their actual power, except that they are of the proper capacity to start the cars satisfactorily.

1583 **Just a Few.**

From Howard C. Porter, Kansas.—1—How are tires measured, inside diameter or outside? 2—Will a 32x3½, a 32x4 and a 33x4 tire fit the same rim? 3—Will 32x4 or 33x4 tires register the same distance on the speedometer as the 32x3½? 4—Under a car weighing 2,200 pounds, what air pressure should each carry? 5—Cannot the 32x4 tires carry less pressure under a car of the same weight than the 32x3½ and yet give mileage in proportion to the price? 6—Will the larger tires ride easier? 7—Would you advise using shock absorbers on a car, and will a car equipped with them ride easier

Digitized by Google

than one not so equipped? 8—Would you advise using them on the front springs and will such use give greater ease of riding for the passengers? 9—Please tell me how I may ascertain the number of pounds pressure exerted per square inch on the piston head in different length strokes in internal combustion engines. 10—Will not the following give the exact horsepower of an engine when taken in connection with the engine speed: Energy per square inch in the piston head, times square inches of piston head, times square of half stroke (crank leverage) divided by the number of required times to be lifted to make one horsepower? 11—If this will give the actual horsepower, please carry out the formula for a 3x5 engine; also 4x4½ engine. 12—Will not the energy exerted per square inch of piston head be more in proportion in a 6 inch stroke than in a 4 inch stroke engine? 13—What are the advantages and disadvantages of a long stroke motor? 14—A short stroke motor?

Reply.—1—Outside. 2—Usually. 3—Speedometer will register lower on 33-inch tires, if correct for 32-inch. 4—The pressure advised by the manufacturer of the tires used. 5—No economy to run tires under-inflated. 6—They should. 7—If we could afford the luxury, we certainly should, and then select the very best in the market. 8—Front and rear. 9—The maximum pressure is approximately four times the compression, absolute, the gauge reading being 14.7 below absolute. Thus with 80 pounds gauge compression, the absolute would be 94.7, and the absolute maximum approximately 378.8 absolute, or 317.1 gauge. By the succeeding queries we judged that you probably referred to the mean or average effective pressure exerted against the piston during the power impulse. In low or medium speed steam engines this is easily computed by means of a planimeter, from indicator card readings, and from the mean effective pressure thus obtained the indicated horsepower is learned. The brake or developed horsepower should be less than the indicated horsepower. In high speed gas engines the indicated horsepower is rarely considered, such power measurements being expressed as brake or developed horsepower. The mean effective pressure in this case is therefore computed from the brake horsepower; or in other words, the only practical and dependable method of finding this factor follows knowledge of actual horsepower at some fixed number of revolutions per minute. The four factors necessary to compute horsepower are mean effective pressure, length of stroke, area of the piston and number of impulses per minute. If the horsepower is known it is a simple matter to compute the actual net mean effective pressure. In fact if the speed factor is unknown, and the others are known, including the horsepower developed, it would be a simple problem to compute the speed. 10—You have not the correct formula. It should be the mean effective pressure in pounds multiplied by the length of the stroke in feet, multiplied by the area of a cross section of the piston expressed in square inches, and again multiplied by the number of power impulses per minute, this final product to be divided by 33,000. 11—Not knowing the speed, the number of cylinders, whether two—or four-stroke-cycle, and either the horsepower or mean effective pressure, this would be quite impossible. Assuming the mean effective pressure to be 78 pounds per square inch, the engines both four-stroke-cycle of four cylinders and the number of revolutions, 1,500 per minute, the 3 by 5 horsepower computation would be $78\times5/12\times(3\times3\times.7854)\times3{,}000\div33{,}000=20.88+$horsepower, and the 4 by 4½ $78\times5/12\times(4\times4\times.7854)\times3{,}000\div33{,}000=37.12+$horsepower. The above assumes that the bore is respectively 3 and 4 inches and the stroke 5 and 4½. By reversing these it may be noted that the horsepower would be different, thus: $78\times3/12(5\times5\times.7854)\times3{,}000\div33{,}000=34.80$ horsepower, and $78\times4/12\times(4\frac{1}{2}\times4\frac{1}{2}\times.7854)\times3{,}000\div33{,}000=37.59+$horsepower. 12—The average mean effective pressure should be less, theoretically the total energy being the same, dividing the total in the former case by six and in the latter by four. 13—Smaller bore, smaller valves which are less liable to warp, less number of revolutions to get the same piston speed, fuel economy, "sweeter" running, and possibility of greater speed flexibility, are a few of the claimed advantages, while among the disadvantages usually advanced are excessive height, possibly excessive piston speed, shorter life, etc. 15—Just the opposite to the reply in query No. 14.

1584 **Impossible to Say.**

From H. H. Hoover, Colorado.—I was coming home from town one day and my engine wasn't hitting good and so I stopped the car, but not the engine, and was working with the vibrators to see which cylinders were missing, when the engine stopped. I cranked the thing but it wouldn't start and I couldn't get it to start. I telephoned back to town and had some batteries brought out and put them on, but nothing doing; I couldn't get the vibrators to sing. I cranked and turned and looked but it wouldn't go. I finally hitched to another car ahead and started off with it. I threw the clutch in and after we went about 20 rods it started up. I untied it from the other car and went on home. If I have made it plain enough to you for an answer, what was the matter? I had plenty of gas and could get a spark from the magneto into the engine but not through the plugs or the vibrators.

Reply.—We do not know the cause of your trouble. Had you told us what car you were driving, or trying to start under its own power, we might have advanced some possible cause. Clouded queries and insufficient information make unsatisfactory replies, not only to those in trouble but to those who might otherwise profit from your experience and our assistance.

1585 **His Chalmers Four.**

From Seymour H. Howell, Pennsylvania.—I have a Chalmers four, which I have only run about eight or ten hundred miles, and I have experienced considerable difficulty with the second gear slipping out of mesh on hard pulls. 1—How can you prevent the grease from leaking into the brake-drums from the rear axle? I have fitted new felt washers in the same but the trouble still continues. 2—How can I remove the rear axle shafts from a three-quarter floating axle? 3—Will the Leak-Proof piston rings give better satisfaction than the regular one-piece rings?

Reply.—There must be something radically wrong with your transmission if the second gear slips out on a hard pull. You should have this attended to at once else it may result in a serious

Digitized by Google

accident to the entire gear set. 1—If the grease is forced out by expansion due to heat, a small hole to relieve the pressure may be drilled into the top of rear axle housing. 2—Write to the manufacturer of the car for full information for disassembling or assembling the axle, and then follow instructions religiously, otherwise you may get into serious trouble. 3—It depends upon various conditions. If the motor is new and the regular one-piece rings are properly fitted and the cylinders are true you probably would not note any difference. In cases where the cylinders are worn Leak-Proof rings have been used very satisfactorily. It is cheaper to put in new Leak-Proof rings than to have the cylinders reground and new pistons and rings fitted and unless one or more cylinders are badly scored their use may obviate necessity of the much more expensive procedure.

1586 **Electric Horn Power.**

From W. B. Oelenschlager, Pennsylvania.—Are there any electric horns made that will operate satisfactorily on Ford cars, using the current from the Ford magneto? As I understand, the current from the Ford magneto is alternating and the voltage output is 12 volts. The standard makes of electric horns are only wound for 6 volts. I have installed a Bosch high tension magneto and I want to use the current from the Ford magneto to operate the horn. Any information that you or any of the readers of this magaizne can give me as to your experience on this matter I will appreciate very much.

Reply.—If you will connect a 6-volt lamp in series with your horn, and you are willing to try the experiment, you can easily find out. We think you would be playing safer to write to the manufacturer of the horn. We have had no experience such as you would like recounted, but know of no reason why a 12-volt alternating current such as the Ford magneto furnishes, would not operate the horn with a 6-volt lamp in the circuit, equally as well as a 6-volt battery of dry cells or accumulators. But you should not forget that this magneto was not designed for such purpose.

1587 **Oxygen for Carbon Cleaning.**

From Newell F. Resseguie, South Dakota.—Has anyone tried cleaning carbon from an engine by running it and feeding in a little oxygen gas at the same time? If this oxygen is explosive enough the engine could be run on it alone and this should clean the whole system without injury, spark plugs, valves and even the muffler, to a certain extent. This has been on my mind for some time but I haven't had the wherewith to try it.

Reply.—We do not know whether just the method you suggest has been employed for the purpose, but oxygen is largely used to-day for burning out carbon. Maybe some of our readers will tell of their experiences.

1588 **Two Cycle Engine Timing.**

From A. P. Fiedler, Illinois.—1—Can you give me, through your journal, the correct timing of the gas distributor on an Elmore 50 horsepower, 4-cylinder, 2-cycle engine, model 37A, built in 1912? This engine does not idle slowly but if two cylinders are short-circuited it runs very slow and steady. 2—Please explain how I can wire a switch from the driver's seat to a K. & W. magneto to short-circuit two cylinders. 3—What makes a 2-cycle engine idle fitfully on a closed throttle when running on four cylinders?

Reply.—1—One of the principal defects of two-stroke-cycle design is inability to idle slowly. When you short-circuit two cylinders you put a load on the two others, as it takes a considerable power to compress the gas in these two idle cylinders, necessitating larger charges in the other two. Therefore while we cannot give you the correct timing of the gas distributor of an engine that is now well nigh forgotten, we believe you must have it approximately correct. 2—If we knew which model of K. W. magneto you are using we might help you, but we think you would have considerable of a task to short-circuit two of the high tension plug cables by means of a switch, or rather a hard proposition to not short-circuit these two cables when you desired to operate all four cylinders. If you have a four-unit coil you could easily short-circuit two of the primary wires leading from the timer to two of the units of the coil, but very few cars outside of Fords to-day use four-unit coils. 3—Want of speed flexibility, due in turn to the fact that approximately one-half the amount of gas is fired twice as often as in a four-stroke-cycle engine, and that insufficient gas is driven into the combustion chamber to rid it of the burned gas. Leak of air into and gas from the primary compression spaces makes an old two-stroke-cycle engine run idle more fitfully than even when new.

1589 **Valve Grinding.**

From A. B. Gentner, Kansas.—I have a Studebaker, which has given me much excellent service, but I undertook to grind the valves myself and didn't get a perfect seat on two of them. I used a Kellogg grinder and a two grade compound, coarse and fine, and I ground them till the pitted appearance was all gone, first using the coarse and then the fine, but I did not get them so they were perfectly air tight. 1—Can you tell me what my trouble is and if I could use anything better than the beforementioned? 2—Is there any way of telling which valve is leaking, the intake or the exhaust, except just listening carefully?

Reply.—1—It is rare that a coarse grinding compound is necessary for grinding in valves. If used at all it should be used carefully and sparingly. The valve should never be rotated a full turn on its seat with valve grinding compound on it. It is best to lift the valve every time the valve is turned back and forth in order to prevent the forming of ridges or scores. If the valve stems are bent even so slightly you can never get a true seat. We make it a practice of never expressing ourselves as to the relative merit of any accessory or tool, consequently this part of your query is unanswered. 2—The experienced person can tell when a valve seats properly by its appearance. It is not infrequently that reground valves will be found to leak worse than before regrinding, as a result, of course, of inexperience and lack of knowledge of the proper method, tool and grinding material.

1590 **A Troublesome Cylinder.**

From E. E. Vorenberg, Florida.—I have a 1914

Digitized by Google

model Herreshoff, equipped with Westinghouse starting and lighting system and Stromberg carburetor. I have recently had it overhauled and motor cleaned out. The piston rings are in good shape and the cylinders are not scored, yet it is almost impossible to keep the intake valve in number 4 cylinder free from carbon. I have to grind it on an average of once a week and always find a small piece of hard carbon under it. I am using a light crystal oil in the crankcase. Can you suggest any remedy for this as I have no trouble otherwise?

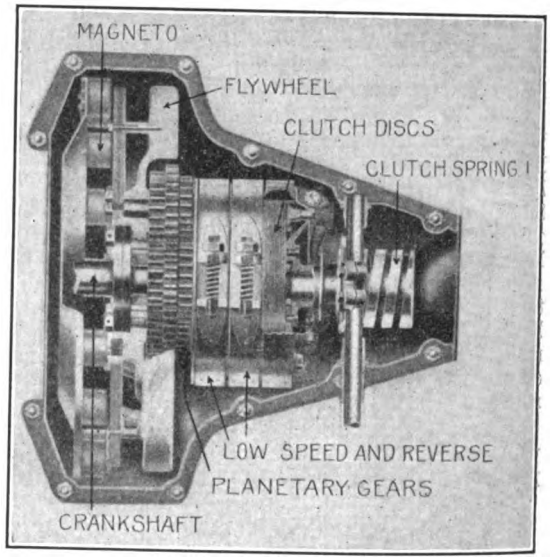
Reply.—The piston may fit too loosely in the troublesome cylinder. Using a heavier or thicker oil might solve the problem. After a season's use an oil suitable for the engine when new is quite often too thin for best results as the piston, rings and cylinders become slightly worn.

1591 **Setting Bearings.**

From G. J. Blancett, Nevada.—As I haven't seen anything in your valuable journal lately in regard to setting up and scraping bearings, I am taking the liberty to ask you to give us a little space as to the correct way this particular piece of work should be done to insure long life and still be free from knocking. In scraping the bearings I rub Prussian blue on the crankshaft and then bolt on the cap and revolve the crank a time or two. I then remove the cap and keep scraping off the blue till the babbitt shows all blue. 1—Is that the correct way? I have been told I shouldn't scrape the blue but I should scrape the white spots. Now which is right? I seem to have good bearings. 2—Is it a good idea to fit a bearing and use paper shims? Is the paper as durable as the brass liners? Please go into detail as to the correct way this should be done.

Reply.—1—Your method of fitting bearings is the proper one, but only a suspicion of Prussian blue should be used, and the bearings should be relieved at their parting on both sides, so the shaft or journal does not touch for at least one-sixth the circumference or periphery to prevent binding at the side, and fillets, or round corners should never touch the bushing. 2—Brush copper or thin brass is far superior to paper, which is liable to burn out should the bearing heat up any.

1592 **Mathematics Trouble.**



From Max. Rahr, Jr., Wisconsin.—When two cars are running at the same rate of speed in miles per hour which of the two engines has the slower piston speed, the one engine of 4-inch stroke, 4 to 1 gear and 32-inch wheel, or the engine of 4½-inch stroke, 3.75-inch to 1 gear and 34-inch wheel. Kindly also explain the method used in figuring the above.

Reply.—In running one mile, or 5,280 feet, the 32-inch wheel would revolve $5,280\times12\div(32\times3.1416)=630.3$ times; the engine being geared 4 to 1 would revolve $630.3\times4=2,521.2$ times, and the piston travel would be, for one mile, $2,512.2\times4\times2\div12=1680.8$ ft. With the 34-inch wheel, the wheel revolutions would be $5,280\times12\div(34\times3.1416)=593.1$; the engine revolutions $591.1\times3\frac{3}{4}=2,224.2$, and the piston travel for one mile would be $2,224.2\times4\frac{1}{2}\times2\div12=1,668.2$ ft. The piston speed would therefore be slightly less in the 4½-inch stroke engine with the 34-inch wheels.

1593 **Planetary Transmission.**

From John P. Hood, Michigan.—Will you kindly illustrate the operation of the Ford planetary transmission in the next issue of your magazine? I thank you in advance for the favor.

Reply.—The two speed and reverse planetary gear employed on the Ford automobiles can perhaps be best understood by the accompanying illustration. This is an easily operated form of speed gear and is naturally popular on small cars. It provides a positive drive and as the gears are always in mesh they cannot easily be injured by careless shifting. In the Ford transmission the clutch which propels the direct drive is composed

Ford Planetary Transmission.

of steel discs and is kept in permanent contact by means of a heavy coil spring. The low and reverse speeds are obtained by tightening the external contracting clutch bands. They are shown in the illustration between the gearing and the disc clutch. The Ford instruction book will probably give you more complete information and we would advise you to send for it.

1594 **Standardized Parts.**

From S. A. McLean, New York.—During the process of separating my car, I have frequently to remove bolts, etc. If I send to the manufacturer I have to pay the long price besides delay in getting parts. I should like to know where in New York I can buy spring shackle bolts drilled and tipped for grease cups, etc. There are so many of these used nowadays they ought to be standard goods.

Reply.—Spring shackle bolts have never been standardized, either in length or diameter. In the best cars these bolts are case-hardened and ground, consequently expensive to manufacture. Except your car is one of which many are yearly turned out, auto part dealers and manufacturers would hardly stock them. Ordinary bolts, if S. A. E. standard threads, can be purchased from accessory dealers in many cases. If U. S. standard threads, screw machine manufacturers usually carry them in stock. Pratt & Whitney standard bolts have U.

Digitized by Google

S. standard threads, and heads and nuts of same size. We do not know whether or not they are regularly stocked.

1595 **High and Low Tension.**

From Harry Stevens, Minnesota.—1—What is the difference in the making of a high tension or low tension magneto? We know the results obtained by using a low and also a high tension, but we want to know what a high tension magneto has or has not that is different from a low tension. 2—Supposing I had a low tension on my car, and also a set of dry cells for starting purpose, and that with my self-starting motor, I am unable to start the engine when the switch is on the magneto, would it be necessary to install a high-tension magneto to make it possible to start on magneto instead of batteries, or would a different starting motor do the business, one that is capable of higher speed? My idea is to find out whether it is necessary to have a differently constructed magneto in order to start on the magneto, or will a higher speed on the same (low tension) one give the same result?

Reply.—1—A true high tension magneto has two windings on the revolving armature, if of the ordinary type, a primary and a secondary, while a low tension magneto has a single low tension or primary armature winding, and uses a jump spark coil to induce the high tension current. Induction types of magnetos use stationary windings with rotors revolving through the fields. If they have low tension windings only they are low tension and if they have both low and high tension windings they are high tension magnetos. 2—Practically all self-starting systems are so designed and wired that starting shall be on the battery and not on the magneto. In some systems the starting circuit cannot be closed with the switch in magneto position. As we understand it, this provision is made to conserve battery energy, for the reason that an engine will start on the battery more easily than on the magneto, and in case of a possible short circuit in the starting system wiring it might possibly demagnetize the magneto magnets if the magneto ignition circuit were open, but as the magneto circuit is short circuited when the magneto is switched off, no such harm can then occur. Our advice is to let well enough alone, to continue to start on the battery and not to attempt the impossible or impracticable.

1596 **Wiring for an Ammeter.**

From Harold G. Stanley, Missouri.—Please explain by diagram in the columns of your magazine how to wire up an ammeter on the Delco system used on 1914 model Buick.

Reply.—Your query is just a little indefinite, in that you do not tell us in which circuit you desire to install the ammeter, the magneto or battery, nor do you tell us the type of the device, whether an ordinary model or one showing whether the battery is being charged or supplying current. We do not wish you to get into trouble by attempting to follow what would have to be indefinite instructions, or which you might not fully comprehend or understand, and it would be absolutely useless to you to have us tell you a lot that you do not wish to know. For these reasons we suggest that you take the matter up directly with the Dayton Electrical Laboratories Co., Dayton, Ohio, who we are quite sure will be able to furnish just the instrument you require, and will be glad to send you a lot of valuable information as to the Delco system used in 1914 Buicks.

1597 **Efficiency Gas.**

From Ray Schroeter, Missouri.—Kindly publish in your next month's issue your opinion of the so-called Efficiency Gas, which you undoubtedly know or have heard of. The people that put this article on the market claim it will increase the mileage of your car 25 per cent. How this can be done by putting one ounce of the Efficiency Gas in your car to every five gallons of gasoline is a problem to me. Kindly let me have your expert's opinion on this. I will watch for it in your next month's issue.

Reply.—We have never heard of Efficiency Gas, which is not used to any extent, if at all, in this locality. As a rule we rather doubt the effectiveness of anything of this sort, but "the proof of the pudding is in the eating," and about the best way to test it is to give it a trial. It should always be remembered that no more power can be got out of anything than there is in it. To increase the combustion power of gasoline by the addition of some other chemical cannot be very easy, because gasoline in itself has an extremely high combustion power.

1598 **Automobile Life.**

From G. W. M., M. D., New York.—I am thinking this spring of purchasing a new car. I have driven a Model T Ford runabout for three years for the purposes of my business. Previous to that for three years I drove a Maxwell. When I disposed of the Maxwell at the expiration of three years, and now in the case of the Ford at the end of a like period the engines, so far as I know, are exactly as good and as powerful as when I began with them. I read recently in one of your answers to correspondents that as the man asking the question which you answered had used his car four years that therefore he could not expect very much of the motor, or in other words, you seemed to imply that four years was about the average life of a motor. Somewhere I have read, and if I do not mistake, in your own publication, the statement that with careful usage there was no reason why an engine should be worn out in a few years and that if properly used, and especially properly lubricated an engine should be all right after ten or fifteen or more years of proper usage. This last statement I have always believed and it has seemed to harmonize with my own personal experience.

My Ford motor is as good to-day, if not better, than when I began to drive it. I am thinking to change to a better and more expensive car, one that in a sense I could make permanent. I would not care at all to do this if I may only look for three or four years as the average life of the engine and if then I must begin to repair and have troubles. Why can I not have a car that will make me a permanent possession? Which of the statements I have quoted is the true one? I do not know whether it is a fair comparison but will say that for seventeen years I wrote upon a Hammond typewriter and it was in perfect alignment when this year I exchanged it for the latest up-to-date Multiplex Model Hammond and I expect to use this machine for the coming seventeen years.

Now that is the kind of service I want in an au-

Digitized by Google

tomobile. Why not? If an automobile engine is only good for three or four years I may as well go right on driving my Ford and stick to the cheaper machines. If, however, I can get a better and more expensive machine and have some permanence about it I would like to do so. I would feel more like spending a lot of money if I could feel the confidence in the automobile that I do in the Hammond typewriter. I should have had some such feeling, as I am a careful driver. But your recent statement which seemed to imply that one need not expect much from an automobile motor at the end of three or four years has rather disconcerted me.

Please let the light of your experience and knowledge of this piece of machinery shine in upon my benightened mind and let me know why I can't have a permanent automobile as well as a permanent typewriter provided I do not make a mistake and succeed in getting a good one this trip.

Reply.—In relation to the period of usefulness of a motor, quite likely the statement referred to, that four years is about its average life, was made with the thought that this is the duration that may be expected before there is a necessity for making repairs, like reboring the cylinders, or fitting new piston rings, and thus the expression might have been misleading. But our correspondent is undoubtedly right in his idea that automobiles would be far longer lived if they received intelligent use and care. We have often marveled that automobile manufacturers themselves seem so willing to minimize the duration of a life of an automobile. We can see no reason for it whatever, unless they have in mind "the other fellow's car," and expect that when a change is made it will be for one of their own make—and of course, the sooner the better. Yet a little reflection will show that the comparison made of a Hammond typewriter machine and an automobile is hardly a fair one. Even when used carefully no other machine in existence has necessarily such destructive uses as an automobile. But there are automobiles and automobiles, just as there are uses and uses, and typewriters and typewriters. The Hammond typewriter machine in its early years was about the most durable one ever made and with hard use it ought to be about five times as durable as an automobile. On the other hand, few drivers of cars have any idea of the tremendous strain put upon them on rough roads, and likewise few pay the attention they should to lubrication and to other important matters connected with them. In many cases a good deal of damage is done to a car when it is first put on the road. Few owners thoroughly understand it, and in many instances it is damaged from pure ignorance or carelessness.

1599 **Engine Trouble.**

From G. W. Martin, Arkansas.—I have model 51 Overland, equipped with Remy low tension magneto and Air-Friction carburetor. Am having trouble with cylinder No. 1 missing when the motor is running idle. The engine fired perfectly up to a few weeks ago, only it did not develop as much power as I desired, so took the motor down and equipped it with a full set of new piston rings. I now have fine compression in each cylinder, and the motor works perfectly so long as on a pull; it never misses a shot on hard pulls up grade, but as soon as I disengage the clutch or start down grade where but little power is required, the first cylinder stops firing and it is impossible to get a single shot from it while idling. I had no trouble of this kind until I put in new rings. I have tested and exchanged the plugs and am positive that the trouble is not there. My carburetor has given perfect satisfaction for a season, and now works perfectly with the other three cylinders. The valves are ground and seated properly. I don't think there is any excessive leaking around the stem of the inlet valve on this cylinder. The caps are all screwed down tight and there is a new gasket in the manifold connection. Wiring is new and in good condition. I can't understand why all the cylinders work perfectly under load but will not while idling.

Reply.—Our reply to W. E. T., Maryland, in this issue, may interest you. If the pistons are too small the fitting of new rings will not always prevent oil working past the rings, as in your No. 1 cylinder, to interfere with proper ignition, but it is more probable that the air leak past the inlet valve stem impoverishes the mixture to such an extent that it will not ignite. The Air-Friction carburetor operates at a much less vacuum than many others, however. You did not say whether this condition was present with the original carburetor, or why you made the change. It would have been interesting to us, as well as our readers, to have had your experience and reasons for changing carburetors.

1600 **Garage Bookkeeping.**

From N. A. C., Mississippi.—I would like to know if you have any system of bookkeeping for a garage. I have trouble in getting all the material charged on the different jobs. I work two men and am out of the shop quite a good deal and I have trouble in keeping up with everything and I thought maybe you knew of some system that I could adopt.

Reply.—Something appeared on page 71 of the March issue that may be of use to the above inquirer. Any reader who has what he considers a convenient, successful and simple way of bookkeeping for a garage will confer a favor by sending a brief description for publication. Failing to receive anything of the sort, we will try and get the desired information from some other source.

1601 **Difficult Starting.**

From J. A. Mandel, South Dakota.—I am a reader of your Automobile Dealer and Repairer and would like to ask a few questions. 1—I have a Ford car and would like to know what make of generator is the most dependable and best for a Ford car? 2—I also have a storage battery and would like to use it for lights on my car. Which is the easiest way to wire it, and would wiring from a storage battery be right, by having it wired in the same manner as for the Ford magneto, to furnish light? 3—I also have an Atwater-Kent ignition system on my car and am having a little trouble. First, starting is difficult. The engine makes a few explosions and stops. Batteries and wiring are all new and well protected from being short-circuited. I have tried all different adjustments on contact points, but this doesn't seem to help any, and after starting the engine when throttling down for idle speed, the motor runs for a few seconds and then dies down to a stop. I have been trying a few different makes

Digitized by Google

of carburetors. I now have a 1914 Holley. Regarding the carburetor will say that when suddenly opening the throttle, the motor seems to load and runs uneven until it is up to a very high speed. There are no air leaks. I had the motor at the Ford factory this winter for repairs. Of course they tried the motor out with their own make of ignition system. I did not send the Atwater-Kent system along, and after receiving the motor and putting it back in the car I put all new wires on and when I wanted to start the motor up I had a very hard time to do it. After I got the motor started it missed and ran very uneven. I cannot locate the trouble in my motor, so please try and help me to locate all these troubles.

Reply.—1—We do not know which generator would be best for your Ford car. Possibly there may be no "best," using that term in the sense of one single generator being better than others. 2—The current generated by the Ford magneto is approximately 12 volts. Wiring for the magneto system may use two 12-volt bulbs in parallel, or two 6-volt bulbs in series. If you are using 12-volt bulbs the wiring must necessarily be in parallel. Your storage battery is probably 6 volts, although you do not so state. If you are to use the same wiring for the storage battery circuit that you do for the magneto, the bulbs would have to be just one-half the voltage. For this reason if you use both circuits it would be necessary to change the bulbs every time you change the circuit. 3—It is our candid opinion that the Atwater-Kent system is not at fault, for the system gives absolutely the same spark at low as at high speed. The fault is more likely due to worn inlet valve stems, causing air leaks to impoverish the mixture, or heavy and hard-to-vaporize gasoline, or to poor carburetor adjustment. Of course there is a possibility that the circuit breaker may not be just right. You should be mechanic enough to put it in proper shape, clean it, etc.

1602 **Ignition Trouble.**

From Geo. E. Knapp, Connecticut.—I am writing you concerning my model 1-3 Maxwell car, made in 1911 or 1912. Some time ago I had new platinum points put on the breaker bar on the magneto and since then have been unable to start it. The breaker bar has the proper adjustment of 1/32 of an inch. The ignition seems to be in time and the valves are in proper time. The engine turns over very hard, but after I have given it a few turns and turned on the switch and gas, I can't get an explosion, only a snap through the carburetor, like a spring slipping over a cog, and a little smoke comes out of the carburetor. Sometimes I get a hotter spark at the breaker bar than I do at others. I have examined the carburetor and find it O. K. The switch and coil seem to be all right and so is the wiring. Will you kindly tell me, if possible, what the trouble is?

Reply.—Your saying that you get "a hotter spark at the breaker bar" seems to settle the matter conclusively—the condenser in the coil is perforated. One mission of the condenser is to prevent arcing or sparking as the current is broken at the breaker bar, in order to prevent fusing or burning of the contact points. If the condenser is in proper shape there will be no sparking at the breaker. Try a new coil.

Removing Studs.

From N. G. Near, New York.—We often read how to remove broken machine screw stubs, but we seldom, if ever, are told how to remove studs that are not broken. A stud usually stands out through a flange, presenting nothing more to the repairman or disassembler than a threaded surface.

We dislike very much to grip a threaded surface with pipe tongs or gas pliers, because of the danger of ruining the threads. By wrapping leather, cloth, or other protective materials around the threads before gripping, it is often possible to save the threads, but this method is not always satisfactory. Sometimes the wrapping slips in spite of all you can do.

I present herewith two little schemes that work very nicely for removing studs without using wrapping materials. In Fig. 1, two nuts, A, are tightened against each other. This is easily done either by the use of two wrenches, two pliers, or even by the use of pipe tongs. Care should be taken, though, not to make the stud tighter. Then by

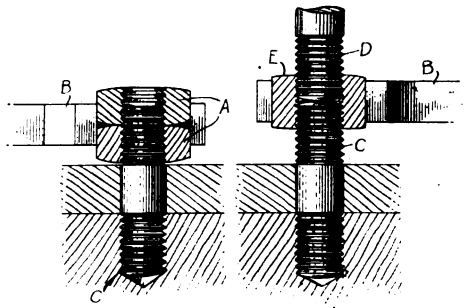


Fig. 1. Fig. 2.

gripping both nuts at once with a single wrench, B, as shown, the stud, C, is easily unscrewed and removed.

Where the stud does not project out a sufficient distance for two nuts it is possible to do the trick with only one nut and a machine screw or bolt, D, as shown in Fig. 2. The principle is almost identical with Fig. 1, except that the two screws, C and D, are tightened against each other within the nut, E. After tightening, the stud is removed by turning the nut to the left. A thick nut, of course, is preferable, because with a thin nut there is danger of stripping the threads. Of the two methods Fig. 1 is preferable because by its use, if the stud is sufficiently long, there is absolutely no danger of stripping threads.

Oversize Tire Service.

From J. G. Click, Indiana.—In a recent issue of the Automobile Dealer and Repairer, M. B. Stine, M. D., Iowa, says he "would like to hear from some of our readers who have had experience with oversize tires." I have had experience with both the regular equipment and with oversize tires and am certainly in favor of the oversize tire. My first car was a model F Buick, equipped with 30x3½ tires, and of course I had my share of tire trouble until I put 31x4 tires on the rear wheels. This was a decided improvement, but as I traded this car before the tires were worn out I do not know the mileage on the 4-inch casings. I then purchased a Buick 27, which weighed 2,550 pounds, and I had 33x4 casings put on all around instead of 32x3½, which was reg-

Digitized by Google

ular, but used the 32x3½ tubes. I drove this car 9,273 miles, using this same set of casings and tubes, with only three punctures and one blowout. In all these miles I never carried an extra casing. When the first blowout occurred I took out the tube and drove to the nearest town on the disabled casing. I bought a full new set of 33x4 casings and sold the old set that had gone 9,273 miles for $9.50 and started out again with a full new set of casings. Those casings are still in service and have gone between 6,000 and 7,000 miles without a blowout.

Must say again that I certainly favor oversize tires.

OVERHEATING.

How It Puzzled the Owner and How He Finally Located It.

From Fisher Ames, New York.—I am much amused and sometimes disgusted at the questions asked in the Trouble Department. Perhaps my experience may be of interest to some car operators. I purchased a new Ford touring car in 1911, and during that summer ran it about 1,200 or 1,300 miles over all kinds of roads without much of any trouble. Early the next spring I took off the engine head and scraped out the carbon and carefully ground the valves and replaced it. I also drained out the old oil and put in new, and put on an oil glass. When the roads became passable I started with a load of five to take a ride. I had gone scarcely three miles before the water was boiling so hard that the overflow could scarcely let the steam out fast enough. I went home and put in a new cylinder head packing, with no better results. I then flushed the radiator and water jacket with a hose and several times later with weak acid solutions, until I was thoroughly convinced that the trouble did not lie there. To make sure I put on a water circulator with but little improvement. I also put on a new style carburetor, an air friction carburetor, and a master vibrator and new set of V-Ray spark plugs, but none of these stopped the trouble, although they greatly improved the running of the engine. In the meantime I diligently pursued the questions and answers in several trouble departments and interviewed every repairman and expert I came across. In every instance I was told that overheating was caused by too far advanced spark, carbon clogged water circulation, dragging brakes, etc. I felt that none of these applied in my case, but what was the trouble? In this way, during 1912-13, I was obliged to run with the hood off and only for short distances on the best roads. One day last summer when scraping carbon from the cylinder I thought I heard a very light tap inside the water jacket, when it was shaken a certain way. Upon closer investigation I located it between the first and second cylinders behind the bolt hole on the valve inside. I carefully put in some hydrochloric acid through the same water hole, and after much shaking and pounding got out two pieces of iron, each about as big as a 5-cent piece and a little thicker. They were round edged and looked as if the iron had spilled when molten. They were probably in the sand used for the core when the casting was made and failed to come out when the core was removed. After this the overheating stopped like magic. So much trouble for so small and simple a cause.

Spark Plug Tester.

From Newell F. Resseguie, South Dakota.—No. 1501 inquiries for a spark plug tester. Here is one I have used for several years to test plugs and vibrators. It is so simple I never thought it worth mentioning. Use ⅛ inch wire, wrapped around a

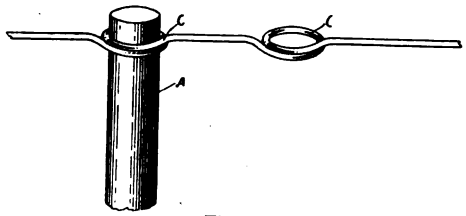

Fig. 1.

rod, A, Fig. 1, the size of the threaded plug end, B, Fig. 2. Make four of these loops, C, one for each plug, as illustrated in Fig. 2. Place the plugs therein. Connect up and set it on top of the engine, D. Mine fits in between two bolt heads, E, making a good connection. Turn the switch and crank the engine and watch results. They may not spark at all. If so the vibrator points may be fouled or too

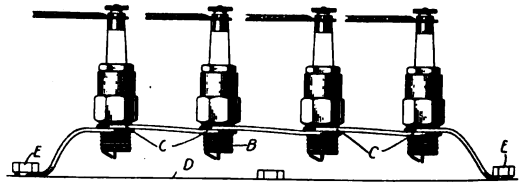

Fig. 2.

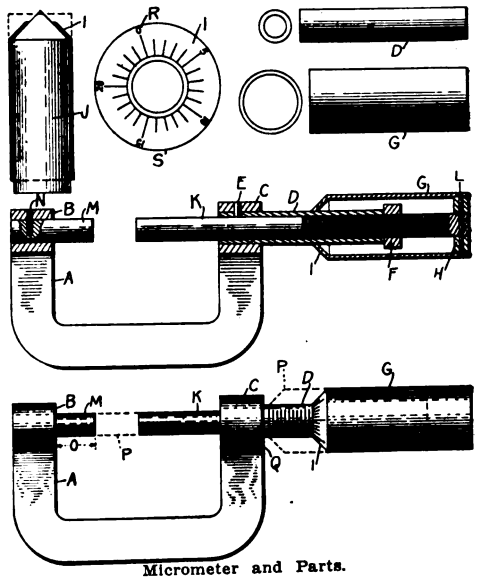
stiff. I get the plugs to spark alike by cleaning, taking them apart, scraping the shell out and setting the points alike about 2/3 the thickness of a dime for the Ford car. In starting the magneto, if the points are too far apart, it is hard to start the engine. Crank it at a normal speed.

NO TIME LOST

When Your Car Is Repaired, While You Regale Chocolate Sundae.

From Felix J. Koch, Ohio.—If your own city does not afford the convenience, drop in on your favorite auto dealer and repairman and give him a copy of the magazine containing this article. Let him get in touch with the city authorities and secure from them such permission as is needed, and you and every other motor enthusiast, as well as all others who depend on the auto for pleasure or profit, will be very grateful.

To begin with, almost every large city in Great Britain, Canada and America insists upon the so-called "parking." That is to say, when Jack Roosa takes his best girl to town in his new motor and draws up in front of an ice cream saloon for a chocolate sundae, he is not permitted to let the auto stand there, blocking travel, but after depositing the lady he must spin with it to some quieter street, park or esplanade, and leave it there to be called for when he desires. Obviously, at first the motor-lovers were opposed to this parking. However, it was found that this simplified things for everyone. Streets, formerly well-nigh choked by resting automobiles, were now open and passable. One could wheel up to just the given door he desired



Digitized by Google

and the cries of disapproval turned to those of approbation. The next step, however, was not so commendable. It was that of the man who takes advantage of the ease with which an auto could be spirited off, when standing thus — ownerless. Motorists returned to the parking place to find their cars missing and no one could say which way they were last seen speeding, nor by whom or when it was taken in charge.

In Cincinnati, not long ago, a party secured from the city council the right to check automobiles at 15 cents per day, and they could remain there as long as you cared to leave them at one stop. This was handy except for the poorer automobile owners, who heretofore had used their cars instead of the street car, and having to pay the 15 cents, found no saving at all. Then someone proceeded to contest the right of the checker to do exclusive business in this public highway and the status was changed. Today checkers are in charge at all hours, checking your car freely, but you are supposed to tip them and they make more now than they did before. The latest convenience incident to this, is the repairing of your automobile while it is parked. Suppose you come to town and suddenly find that your engine is missing, or you get a puncture or a blow-out, or you find that your valves need grinding. The nearest empty store to the parking place is secured by the checker and in this he establishes a first-class repair shop. You come to town and go to your respective places of amusement, business or whatever it may be, after parking your car as usual. Meanwhile, the repairman does as much repairing on your car as is necessary, or as is possible in the time you may allot him, and tomorrow or the next day he will finish the job when you check your car with him. It is far handier than having to drive to some other repairman and have your car tied up while he does his work at his leisure. So it pays, even when for so much the checker looks over your car, which seemingly is in good condition, and anticipates a trouble and puts in the "stitch in time." The same repairer finds that he does well in fitting up a window and selling accessores, such as jacks, tires, patches, buckets, auto trunks, tools, etc. He has an opportunity to draw your attention to these which other stores haven't and he doesn't let the opportunity slip. Why the plan is not carried out more generally is uncertain, as it both pays and pleases all parties concerned. If your own city hasn't attempted it, let some one get busy. He is sure to have more work than he can attend to.

Easily Made Micrometer.

The sketch is a design for a micrometer that will read to a thousandth of an inch, and will be found a very handy tool. The cost of a micrometer is so high that it prohibits many from buying one. This one illustrated will meet all the requirements, and can be made at a nominal cost. The frame, A, is made of strap iron ½x⅛ inch, and the ends, B and C, are rolled over to form an open ring. The opening in B is ¼ inch, whereas the opening in C is ⅜ inch in diameter. Then take a piece of brass tubing, D, ⅜x2 inches, and fasten it in the ring, C, by a pin, E. On the other end of the tube, D, braze upon it a nut, F, tapped with a ¼ inch tap. Now take a larger piece of tubing, G, large enough to clear the nut, F, to act as a sleeve. In one end of the sleeve, G, place a plug, H, with a ¼ inch hole, and bevel the other end, I, about 45 degrees. This can be accomplished by placing it over a piece of wood, J, and hammering it. Thread a 4 inch rod, K, about half-way, to fit the nut, F, and run a pin, L, through the sleeve, G, plug, H, and rod, K. The piece, M, being ¼ inch. It projects beyond the frame ½ inch as indicated at O. Turn the sleeve, G, down until the screw rod, K, comes against the piece, M, as shown in the dotted lines, P, and make a mark, Q, on the tube, D, to register with a zero mark as shown at R, on the sleeve, G. Turn the sleeve one revolution and make another mark and continue this operation until the micrometer is opened to its full length. The bevel, I, on the sleeve is marked into

Micrometer and Parts.

25 parts, numbering every fifth graduation, beginning with zero, as shown in the view, S. One complete turn of the sleeve, G, represents 1/40 of an inch; 1/25 of a turn equals 1/125 of 1/40 or 1/1000 of an inch.

Praise for the Mitchell Car.

From Samuel M. Sutton, Pennsylvania.—I have been driving a car for ten years and am one of the lucky ones. I have had no road trouble of any kind. I am driving a Mitchell 6, and think they are one of the best road cars on the market for hill and mountain driving. I toured over the mountains to Gettysburg, through Maryland, Baltimore, Washington, D. C., and all through the East on the one trip. We ran 1,050 miles and only had about seven minutes' stop in the entire trip. At this time we were changing a tire as we had a blowout. We had the pleasure of seeing almost every make of cars hung up on the mountains from over-heating and carburetor trouble. We did not make a single adjustment on our Mitchell. Any person wanting a machine for road work can't go wrong on purchasing a Mitchell. I have had four years' experience with this make. We did not have to go in to low speed on any mountain on our journey. For the benefit of new drivers touring over the mountains I will advise them not to try to overheat their cars by seeing how far up a hill they can go on high speed. I have always found it best to change before

Digitized by Google

starting up a hill, for you have a chance to get your engine working well and it will pick up speed on any grade by changing at the foot of a long grade. There are many drivers to-day that think they can make any hill on high, but my advice to all new drivers is to be careful on hills and you won't have so much gear trouble as you will have when trying to change gears when the engine is running so fast. When driving in mud I find that four chains are very useful. Many drivers only use two chains, but you will find a great many of them along the roadside, in the ditch. It is best to be on the safe side.

DIFFICULT MOTORING

Troubles Experienced in the Hills and Valleys of Darkest Arizona.

From M. A. Foster, Arizona.—I see many questions asked and answered, which any motor driver can derive considerable information from, and I have often thought that if some of those fellows were located here in the jungles as I am, with hundreds of miles between them and the information, what they would do? I have been up against propositions when I would have been glad for the information that I could have had for the asking, but as time would not permit me to wait to get this information, I found that I must get busy and solve the problems myself. I am a hundred miles from a garage or other repair shop, and necessarily I must do my own repairing. I have owned and driven four different cars in and around Denver, Col. I never had any engine, differential or transmission trouble. All the trouble that I experienced in driving cars in Denver was tire and ignition trouble. But just listen: Since I have been engaged in motoring in the jungles of Arizona, I have experienced every trouble that is on the map of motoring, and some that isn't. When I get out fifty miles from any place, except bad mountain roads and a breakdown, or have some engine trouble, then what do I do? Write to some journal and ask what to do to get my car to going? Not much. I would get very hungry waiting. I just take in the situation clearly, determining what has to be done and then get busy and get the car in condition to get home at least. I find this is a good schooling.

If some of you people that drive mostly on graded roads and paved streets could see the roads here in the jungle, then you would say to drive a car over such roads could not be done. I thought so when I first came here, but I saw that some few people were driving a motor car over these roads, and I believed that I could do the same. Remember, we have no such a thing as graded roads here—just an opening cross the hills and valleys. We have very few bridges and have to cross streams of water 18 and 20 inches deep. Most cars in this locality are Fords, as the Ford appears to stand the mountain climbing and the mud baths that a car has to go through in this country, better than the heavy cars. The Ford car appears to be just about the right weight for the mountain climb and the heavy roads after a rainstorm. Sometimes we start on a trip and get 100 miles from home and get in a hard rainstorm. We can't stay there and wait for good roads and weather, for usually there is no place to stay, so we have to split the mud and make the best of it. We get up against propositions where we have to be able to make a car do a little more than it was built to do, and if we can't, then we have to stay there until some team comes along and pulls us out.

Now some of you people back in the States may think I have exaggerated the matter a little, but it is much worse than I have told it. There isn't a car in this locality that has been used for the last five months, and the prospect is good of no use for at least two months yet. The snow on the mountains is from one to ten feet deep, and we can't get out any distance either way from here without crossing the mountain. I have seen the inexperienced try to drive a car through this country, but the result was a serious break or wreck, with bearings melted out, connecting rod punched out through the side of the engine, or the engine hot and stuck; in fact every trouble that exists and many that don't exist back in a civilized country. The writer has experienced most of those troubles. I have always been able to bring my car in on its own power, except once. This was when I sheared off one of the keys in the differential gear. I cut the key out of a piece of steel that had been used on a brake box car. With the tools that I had with me, it was a very slow job, but the nearest garage was 23 miles away, and my car would not run at all, so you see this is how I learn repairing. This was the first time that I had the chance to see a differential gear, and a very unwelcome one it was at that time, being 65 miles from home, without tools or material for a job of this kind.

Simple, When Found.

From C. W. Case, Kansas.—I have been reading lots of the boys' experiences and I will tell one of my own. I am a repairman on gas engines for the Union Pacific Railroad. I have had all kinds of trouble with cars. I have had those queer knocks that I read about in the paper and misfiring, but I always found the cause and they were all very simple when found. The other day a man came in with a car and said it was "shorted" and would not run. I examined the wiring all over and found everything O. K. I got in the car and it started all right and ran 200 yards and stopped. I got out and examined everything but found nothing wrong and I got in again and it started all right and ran about the same distance and stopped again. The car did this trick for me about a half a dozen times and when I could find nothing wrong, I unscrewed the gasoline feed pipe from the carburetor to see if the gas was coming through the pipe and it was all right, so I got down and looked in the carburetor and there I saw my trouble. It was chock full of all kinds of trash and I cleaned it out and the car was all right. The next time I have a car that acts that way, maybe I will find the trouble some place else. There is always something to learn about a car every time you run one.

That Clutch Trouble.

From D. E. Martin, California.—If Mr. Carmichael of Florida, No. 1526, will (1) throw out his clutch, (2) touch the foot throttle slightly to speed up the engine and the driving discs in the clutch; then throw into low, he will have no trouble in engaging his low gear, even in cold weather, when oil in the clutch is thick. The reverse gear will grate

Digitized by Google

the same as the low if he attempts to go into reverse. Driving and driven discs cling together even with clutch out. Speeding up the engine a bit by means of the foot throttle speeds up the driving discs, or one-half of the clutch and effectually separates these from the driven discs or other one-half of the clutch as nothing else will do, and hence the clutch stops spinning. I have a Hudson 33, 1912, and she is a peach, but my clutch acts the same as No. 1526.

WORN VALVE GUIDES AND STEMS.

The Trouble They Cause and How They May Be Remedied.

From C. P. Shattuck, M. E., Rhode Island.—One of the most difficult sources of trouble to locate in old motors is the cause of the engine missing when throttled down, and this is particularly true when the motor is equipped with a modern type of carburetor. As a rule the motorist brings his car to the repairman with the carburetor completely out of adjustment, and instances are recorded where the owner has tampered with the contact points of the magneto or altered its setting in an attempt to correct the trouble.

The general cause of missing when the motor is throttled is not as a rule difficult to locate but there

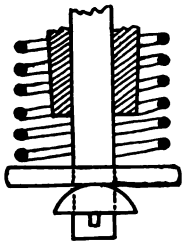


Fig. 1.

are other factors which are not taken into consideration, such as the seating of the valve springs, their retainers and the valve tappets. It is well known to the expert that worn guides and valve stems are responsible for the failure of the engine to throttle because air is drawn past the stems on the suction or intake stroke, diluting the mixture.

Wear of the valve stem and the guide is often due to side pressure present with the commonly used type of helical spring, and because in old motors the spring cup or collar cannot compensate for any unequal pressure that may be exerted upon it by the valve spring. That this side pressure is responsible for undue wear is shown by the drawing at Fig. 2 in which the dotted lines illustrate the amount of wear in a valve stem examined by the writer recently in which instance it amounted to almost 1/32 inch. No amount of grinding will remedy the trouble; in fact, grinding will only aggravate it because the grinding is done with the valve stem in a position which it will not maintain when the spring is in place.

The helical type of valve spring is often so made that the ends of the coil do not bear more than 90 degrees of its circumference, obtaining an unequal pressure which is increased 100 per cent. if the other bearing end of the spring is on the same side. If this unbalanced pressure be present in a valve spring of large diameter, mounted on a valve stem of rather small diameter, it is possible that after the spring had seated the valve it could so lift or tip one side of the valve as to allow the gases to escape during both the firing and compression stroke. If the pressure of compression or that of the explosion exceed that of the unbalanced spring, the valve would seat all around, but a loss of the mixture would be probable before this took place.

Much of the side thrust is due to the design of

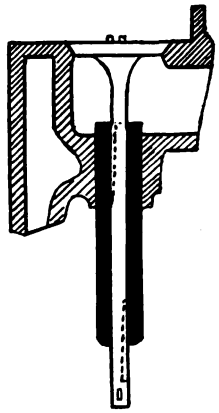

Fig. 2.

some tappets which, when they lift the valve, push it to one side; that is, the lifting effect is not applied vertically but sideways, causing wear of the tappets and their guides which increases the unbalanced pressure of the valve springs.

It may not be feasible to alter the valve spring, but when it is of large diameter and coarse pitch it may be that the balance of the spring can be improved by grinding the ends, especially if these be not at right angles to the stem. In the opinion of the writer this unbalanced pressure could be compensated for by fitting a washer having a spherical surface between the pin or key and the valve spring

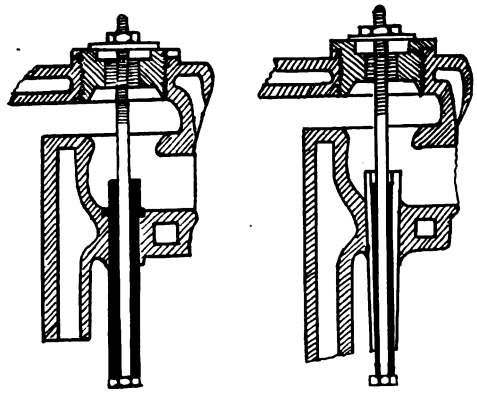

Fig. 3.

collar as shown at Fig. 1. This device would serve another useful purpose especially with old valve springs, in that it would increase their tension. The spherical washer need not be over 3/8 or 1/4 inch, and its fitting would not require any alteration in the design of the retaining pin.

The most effective remedy for badly worn valve guides and stems is the fitting of new members, but frequently the owner of an old car objects to the cost or it may be that the parts cannot be secured.

Digitized by Google

If the guides are integral with the cylinder they will require enlarging to take a bushing, provided there is sufficient metal. When the stems are worn as shown at Fig. 2 it is advisable to fit new ones. The method of procedure will vary according to the design and the inclinations of the owner.

Fig. 3 shows a simple contrivance for removing and replacing valve guides when these members are a drive fit and not screwed in. It consists of a threaded bolt of sufficient length and small enough diameter to pass upwards through the guide and through the spark plug valve cap. A washer is threaded on to the top of the bolt and a nut screwed down upon the washer. The lower extremity of the bolt carries a nut as shown. This device will afford a pressure that will generally loosen the guide,

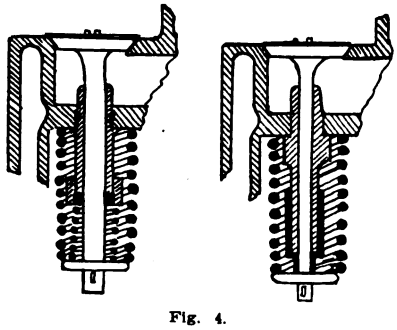

Fig. 4.

but when it is frozen it may be started by screwing up the butt, then tapping the lower end of the bolt with a hammer. The use of a punch and a hammer for driving out a bushing is not recommended as burrs will be set up on the walls of the hole, making it difficult to fit the new guide.

When it is not possible to fit a bushing or the owner does not desire to incur the expense of the work, either of the two methods shown at Fig. 4 may be employed with success. That at the left consists of a form of thimble turned up from a piece of brass or bronze to fit over the guide and it is filled with asbestos wicking saturated with graphite and grease. If the guide be badly worn its lower end should be beveled off so that the wicking will be packed in, obtaining the effect of a packing gland. A light spring is utilized to retain the thimble in place.

When there is insufficient room between the end of the guide and the collar the arrangement shown at the right in the drawing at Fig. 4 is more satisfactory. It comprises a thimble turned up from a piece of cast iron, constructed to slide easily on the guide and to be a push fit on the valve stem. As the contacting surfaces are fairly large and can be lubricated, they will indure sufficiently to warrant the expense of making the thimbles, which is small.

How They Get Business.

From Felix J. Koch, Ohio.—The chase after business these days, with competition growing ever more and more keen, is putting men to using their wits, and some interesting methods of securing the trade are hourly being brought to notice. Not the least successful of these is that of an automobile service concern in Cincinnati, which is enabled to give assistance when you are far from their shop. It obtains the names of all car owners from the State Licensing Board, and has furnished them with a stamped, self-addressed postal, bearing the date, name of the party mailing, his address, the license number on the car, 'phone of owner, make of car, year and model, spaces for tire sizes, both front and rear wheel, and whether clincher, quick detachable or straight side.

As soon as this card is received back from the owner it is properly numbered and filed away. In return, the sender will receive a card bearing his number, and this number is all he will need to give the repairer over the 'phone, together with the location of his breakdown. As soon as this call reaches the garage, one of its free service cars will be dispatched to him immediately to help him out.

"This organization," says the promoters, "is equipped to give to motorists of Cincinnati and vicinity a lift in time of tire troubles. Simply fill in the card and file it with us. Should you ever have any tire trouble, within a radius of ten or a dozen miles from the city, telephone, and no matter what the hour, day or night, we will hurry to you the help you need, in one of our fine, new fast-going, free service cars. We will bring gasoline or oil, should you be without the same. What is more, we change, deliver and apply tires or tubes to your car a dozen miles or more from our store at any time, day or night, at exactly the same price at which we would sell the same item across the counter."

Needless to say, hundreds of persons have already taken advantage of this new service.

A Spring Leaf Separator.

We know how much easier a car will ride when the springs are well lubricated, but to do this it is well to have a tool to hold the leaves of the spring

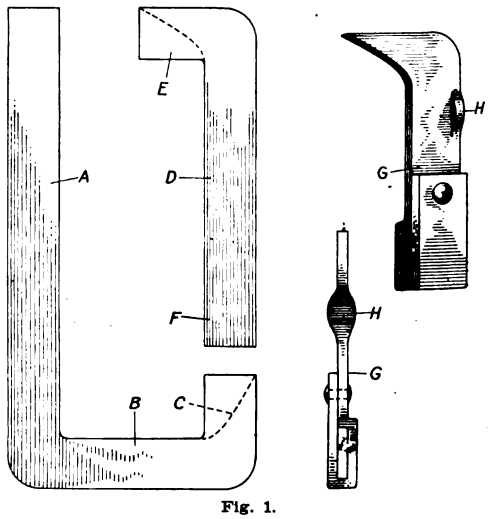

Fig. 1.

apart, while the lubricating operation is taking place. This tool can be easily made. Take an old carriage tire and cut off about 14 inches of it, as shown at A, Fig. 1. Then bend as at B, and with a hack saw cut on dotted line, C. Next take a second piece, D, and bend the end, E, and cut also with hack saw on dotted line, as you did at C. Now take the piece, D, and shape the end, F, so it will look like G, and place it on an anvil and strike at H to

Digitized by Google

spread a flat surface. Place G on A, as shown in Fig. 2. Then bend the end, I, as shown. J is formed around a square nut, K, which is held in position by pins, L. The bolt, M, is placed in position as shown, and the nut, N, is drilled to admit a piece of steel, O, driven in and held in place by pin, P. This will enable the user to screw the bolt in the nut, K, and

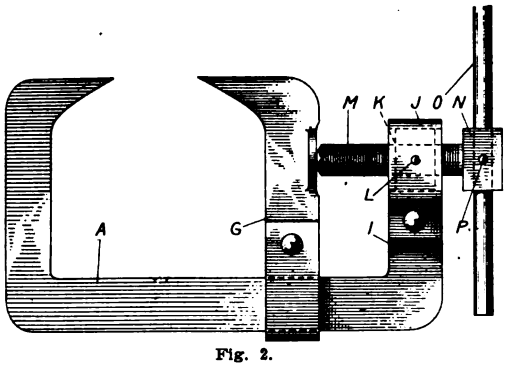

Fig. 2.

move the arm, G, forward so as to engage between the leaves of the spring, making it an easy matter to keep them well lubricated.

Care of Storage Batteries.

Service Engineer M. Hegelstine offers some good advice to Studebaker dealers on the care of storage batteries:

"Frequent and systematic inspection will forestall trouble almost entirely with storage battery," he remarks. "A dealer will find it very easy to follow the necessary steps in the care of a storage battery. He should educate new owners to follow the same plan. It will save him annoyance.

"A storage battery should never be allowed to go more than one month without being inspected. An inspection every two weeks is more to be desired.

"The solution in the battery cells must cover the plates by at least half an inch. If the solution is lower than half an inch above the plates, add pure water. By the term 'pure water' we include carefully filtered rain water, distilled water, or water from melted artificial ice. By far the greatest amount of battery trouble is caused by leaving the plates without a covering of solution.

"Do not allow anything to lie on top of the battery. Especially in the summer, do not pack anything around the outside of the battery. There is heat generated during the charging and discharging of the battery. The battery has been purposely placed in the open to allow radiation of the heat. A charged battery will not freeze.

"If your car is not operated for a period of two weeks, make a hydrometer test, and if required, charge the battery to the proper reading (1.280—1.300).

"On a car laid up for the winter, a battery should be given a hydrometer test every two or three weeks and battery recharged to prevent damage to plates and freezing.

"Never add acid to the solution. The acid cannot evaporate, whereas the water does evaporate. If you add acid, without it having been lost through leakage from a cell, the solution becomes too strong and the plates are damaged.

"Keep the terminals clean and tight. This precaution is based on the same reason that all electrical connections throughout the car must be tight and free from foreign substances.

"Clean the top of battery occasionally with a damp cloth (not wet). If this is done there will be less chance for the collection of dirt.

"With every inspection of the battery or when you have reason to believe that the battery is not fully charged, test with a hydrometer.

"A hydrometer should be in the possession of every dealer. A first class one can be purchased almost anywhere for $2.25. A battery is fully charged if the reading is at any point from 1.280 to 1.300. If the reading is below 1.250, the motor should be operated to charge the battery up to 1.280 or higher."

Front Wheel Alignment.

From Oscar O. Romundstad, Wisconsin.—The wheel alignment given in the January number doesn't correspond with the teaching I got in the shop, but that is not saying it is wrong, for auto construction changes faster than we can learn how to fix and adjust them. Most cars have the front wheels set so they are wider at the top than at the bottom, and such wheels must toe in or have "gather," as the wagonmaker calls it, and the amount of gather depends on the set and diameter of the wheels. No car with front wheels leaning out will steer well. The front axle should be put in so that the king bolts lean backward. It will be noticed that by this arrangement the inside wheel cuts a smaller circle in turning. But this is not the only way the inside wheel is brought to making a shorter

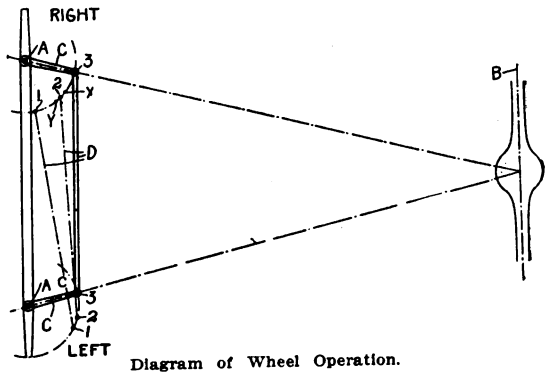

Diagram of Wheel Operation.

turn, for in looking over your car the steering arms on the stub axle will be found to be put on so a straight line from the king bolts, A, to the center of the back axle, B, will pass through the ends of the steering arms, C, or nearly so, and these two being connected by a rod, D, it is plain that in turning either to right or left the inside wheel will be swung the most. The sketch shows three positions of the steering rod, marked 1, 2 and 3. The distance from X to 2 is the amount of travel given to the right side over the left in turning to the right at the angle shown by No. 2, and the distance between Y and I is increased in travel of the right side over the left in turning to the right to the angle shown by No. 1. When it is remembered that the spindle and steering arm are always in the same relation to each other, it will be seen that the inner wheel in turning will have a reason for making a shorter turn.

Automobile Dealer and Repairer

A Magazine of condensed and compact information for busy readers.

Member of the Audit Bureau of Circulations.

PUBLISHED THE MIDDLE OF EACH MONTH BY

THE MOTOR VEHICLE PUBLISHING CO.

71-73 Murray Street, New York

Telephone, 6765 Barclay Post Office Box 654

Entered as second-class matter at the Post Office in New York City.

M. T. RICHARDSON, President and Treasurer — F. R. WHITTEN, Secretary

A. A. HILL, Editor

F. R. WHITTEN, Advertising Manager

E. DAYTON, New England States — H. F. LUDINGTON, Illinois, Indiana, Michigan Wisconsin and the West — F. M. DAMPMAN, New York, New Jersey, Pennsylvania, Ohio

TERMS OF SUBSCRIPTION.

One Copy, One Year, Including Postage.....$1.00
One Copy, Six Months.....60 cents
Single Number.....10 cents
Foreign Subscriptions.....$1.50, or 6s. 3d.

Remittances should be made by Express Money Order, Draft, Post Office Order, or Registered Letter. Foreign remittances, where possible, by International Money Order.

ADVERTISING RATES MADE KNOWN ON APPLICATION.

NEW YORK, APRIL, 1915.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

SIGNING LETTERS.

It is a curious fact that many men will write a letter so distinctly that every word is intelligible, and yet attach their signatures in such a way that nobody can decipher them. This is done frequently in typewritten letters. One business man of our acquaintance has adopted the plan of having all letters signed by the typewriter and then he signs himself underneath so no mistake can be made by the recipient of the letter. This plan may be utilized to advantage by a great many business firms.

NEW THINGS.

The number of new devices and accessories appearing in the automobile field are as wide in range as they are interesting. They would be little short of marvellous were it not for the fact that the automobile industry or art is still practically in its infancy, and improvements may constantly be expected. Thousands of bright men are intently studying the subject, with the result that improvements upon improvements are appearing, until no one can foretell just when the business may be a "closed art," as they say in patent office circles.

Of course our readers are keenly interested in this development, and in order to keep posted as to just what is on the market they should closely watch our advertising pages each month or they will overlook many things of interest and value to them.

The automobile of to-day is as much superior in the sense of economy and usefulness to that of five years ago as the modern war vessel is to the old "Monitor" and "Merrimac" of whilom fame. We have stated, and it may be confidently repeated, that in its application to business and pleasure the automobile will not only continue to displace the horse, but it will soon make such inroads into the use of the street and general railway service, that it will be little short of revolutionary. The "jitney" 'bus system is spreading like wildfire, and for short haul commercial and passenger service, it is constantly increasing and extending. In each instance there is a gain in economy and convenience.

FOOD FOR THOUGHT.

Florence is one of the richest cities in Italy. It has one automobile to every 6,000 of population; Iowa has one automobile to every 20 of its population.

Our foreign markets are well enough. Let us get all the trade from them it is possible. And just now, when about all of Europe is engaged in war, this market, especially as it relates to military needs, is considerable. But when the war is over, as all should devoutly hope it soon may be, how much foreign trade will we then get? With the war countries prostrate, and every worker, including the discharged soldiers, destitute, and simply crazy to go to work and earn a living—and a meagre one at that—how much of foreign goods can they be expected to purchase? At that time the prosperous State of Iowa and of many other States, will furnish a better market for goods than the entire continent of Europe.

But please do not forget: The market depends upon the condition of the people, the condition of the people upon the rate of wages, the rate of wages upon the hours of work. Of course, if this enforced idleness continues, and the needs of the unemployed are used to compel those who are employed to accept such wages as employers wish to pay, thus increasing pauperism and want, the home market will suffer.

In this city of New York, it is reported that $20,000,000 annually are now being expended for charitable purposes. Thousands are being "fed" upon two cent meals. We trust it may not be forgotten that charity literally grows and multiplies by feeding upon itself. It is nearly as contagious as the plague or smallpox, and quite as deadly.

Of course, the foregoing is both desultory and fragmentary, but it should at least supply a text for thought.

A NEW ELECTRIC CAR.

Charles P. Steinmetz, the famous consulting engineer of the General Electric Company, of Syracuse, N. Y., claims that the gasoline car will soon be superseded by the electric vehicle.

It appears that a new invention promises to very much reduce the weight of the car. It will do away with the differential, the shafting from the motor to the rear axle, the bevel gearing, and the housing for these parts. Moreover, when the car coasts down hill, the motor is turned into a brake, and acts as a generator, putting current back into the battery.

Mr. Steinmetz thinks that with these improvements the weight of the electric car may be brought under 1,000 pounds, thus much reducing the consumption of propelling power.

All these things are worth noting. On the other hand, the gasoline automobile will not be easily displaced, even though all the foregoing claims may be

Digitized by Google

ultimately demonstrated. The amount of electricity generated by the momentum of the car while descending a hill will not be important, and on the road or street there are on the average just as many and just as steep hills to ascend as there are to descend. The lighter weight referred to is attractive in the case of a car that has no more speed than the existing electric car, but for high speed, light weight is just a bit imprudent. The frequency of recharging the batteries seems not to be overcome in the consideration of this potential electric car.

GREATEST GOOD TO THE GREATEST NUMBER

Occasionally some reader complains because we have so much about the Ford car in this magazine, while on other occasions some one reminds us that we seldom have anything about the car that he himself owns. It is obvious that much should be published concerning the Ford car. It is unusually low priced and widely used. Although it undoubtedly gives good satisfaction compared to its cost, if it were as enduring and luxurious as a high priced car there would be no advantage whatever in owning a high-priced car. Moreover, it naturally is owned and purchased mostly by the great middle class who not only drive their own cars, but who also want to thoroughly understand their care and repair. Owners of high-priced cars often leave the question of care and repair to others, and thus information is often achieved less directly and at greater cost.

But information in relation to one automobile applies to a greater or less extent to most others. All automobiles have engines, ignition systems, transmission systems, lubricating systems, wheels, tires, paint, varnish, etc. Information concerning any of these is practically universal. We have no personal interest whatever in the Ford car. To the best of our knowledge, the firm manufacturing it has never paid us a dollar for any purpose whatever, although it goes without saying that this fact has no influence whatever, one way or another.

Our aim is to be of service to our readers. Sometimes it is felt that such service falls short of what it should be, but if this be the case it is not because of lack of effort. There is no better way to edit a magazine than to follow the old injunction of supplying "the greatest good to the greatest number."

"REASONABLE COMPLIANCE."

According to a reliable newspaper report, the Commissioner of the Department of Motor Vehicles of the State of New Jersey, has caught the more or less prevalent feeling that laws are not made to always be lived up to but to be adapted to convenience. He is quoted as saying:

"It has been the custom of the Motor Vehicle Department and of the police departments generally to be satisfied with a reasonable compliance with the speed regulations as outlined in the motor vehicle act. In fact, it has been the general police practice to allow any person to operate an automobile in the open country at the rate of 30 miles an hour and in the cities at the rate of 18 miles an hour without becoming subject to interference by the officers."

But the motor law of New Jersey fixes the speed limits at 12 and 25 miles an hour, and any greater speed than this is not "reasonable compliance" nor any other compliance; it is simply law violation.

If the limit of 12 and 25 miles an hour is unjust and a hardship, why, let the law be repealed or the speed limit be increased to such a rate as may seem to best promote the public welfare. But let there be no violation of law, and especially of a law so explicit that no one can violate it unknowingly.

Law violations are a bad, not to say dangerous, habit, and they grow on one something like the drink or the drug habit, dulling the moral sense and weakening the will power. In what may be termed fairly lawful communities, few appreciate the value of strict obedience to law. It is only when one is for some reason obliged to live in a country where there is no law that he begins to realize the blessings of a system where "right makes might" rather than one in which "might makes right."

PROMETHEUS BOUND.

Zeus bound Prometheus to a rock where his liver was pecked out by an eagle during the day only to grow again at night. It is devoutly to be hoped that the interminable commissions which are so fast encompassing public and private enterprise with rules, regulations and mandates, will not inflict the same punishment upon business. For if the liver of enterprise be once destroyed it will require more time than a single night for it to grow again.

Of course, no one can justly object to rules or orders that give promise of promoting the public welfare, but an interference that shackels or puts business in a straight-jacket should be zealously guarded against. It is contrary to that freedom which is the highest expression of self-government.

Although the supervision of existing business enterprises by public service commissions may be withstood, it can but make those who contemplate new enterprises apprehensive to the point of abandonment. Just at this time and under these conditions there should be no "wet blankets" to enterprise, whether they are of either a public or private nature.

The rapid growth of the "commission" form of government is fast becoming really alarming.

Trying to Standardize Treads.

In response to the insistent demand from Southern dealers as well as from the manufacturers generally, an effort is now being made by the National Automobile Chamber of Commerce to bring about the standardization of vehicle tracks in this country, which of course will mean lower manufacturing costs and ulitimately lower list prices to buyers of cars.

One of the difficult things in the making of motor cars has been to care for the wide treads which some parts of the South have deemed necessary. Now comes a demand from the legislatures of standard tracks, while the carriage and farm wagon manufacturers are appreciating the advantages that would come from standardizing the tread of four feet eight inches.

Dealers in the South have for a long time advocated the abandonment of the so-called wide tread, claiming it was unnecessary with the improved road conditions, while it so embarrassed the car manufacturer who seldom was able to make deliveries of

Digitized by Google

cars to the dealers on time; thus resulting in a loss of trade.

From the manufacturers' standpoint, the making of wide treads has been a source of trouble and expense, because it necessitated the carrying of large stocks of extra parts, the making of special axles, special fenders, and in some cases, steering gears. Invariably he guessed wrong as to the number of cars to be used in the South, and cars also always came through too late for the southern selling season, besides being a disturbing factor in factory production.

On the other hand, there are some places in the South like Southern Florida and Southern Georgia where there is still a demand for the 60-inch tread, and this demand is being supplied, although the dealers state that another year or so should see such improvement in road conditions that the standard tread will be in demand.

It is expected that the ground work can then be laid for a thorough investigation of the subject, so that later the engineers can bring about a standardization of tracks at four feet eight inches, eliminating the narrow sleigh tracks and the wide vehicle tracks deemed necessary. This would not affect the very wide tracks of heavy trucks, both motor driven and horse drawn, which probably will continue to be offered in tracks necessary for carrying bulky or heavy loads.

The subject is most important because standardization will materially lessen the cost of manufacture and ultimately bring vehicles of all kinds to the consumer at lower prices.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Drives Machine Through Ferry Railing.—At Ironton, O., one little boy was drowned when a party of seven crashed through the railing of ferry. It appears that the ferryboat tender asked the driver to move his car and in doing so the car started and failed to stop in the proper place but crashed overboard.

Struck a Boulder.—Near Butte, Mont., a man was instantly killed when in making a sharp turn he encountered a boulder, upsetting the car and throwing the man 17 feet and breaking his neck.

Killed While Taking First Lesson.—A man was instantly killed at Woodland, Cal., while taking his first lesson at driving an automobile. The inexperienced man induced the driver to let him handle the machine. A horse and buggy suddenly loomed up out of the darkness in the flare of the headlights, causing the man to lose his nerve and control of the car. The car turned turtle, throwing one of the men clear of the car and crushing the other beneath it.

Kills Man and Sneaks Away.—At Akron, O., a man was borne down upon by a big touring car which flashed out of the darkness without warning. He was knocked several feet, crushing his head and killing him instantly. It is stated that the car sped down the street away from the scene with open throttle and dimmed lights.

Tracks Obscured.—Four children were killed and two adults severely injured as the result of accident at Albion, N. Y. The owner and driver failed to see an approaching trolley car running at express speed, because the view of the tracks was obscured by buildings. The rear wheels of the automobile were struck by the trolley car; three of the occupants were thrown fifty feet, landing on the track; the auto was hurled into the ditch; one passenger landed in a field and another in the ditch. One little girl was found dead near the machine. If motorists would "stop, look and listen" in crossings where the tracks are not visible, these horrible accidents would not occur.

Dog Wrecks Auto.—At Manila, P. I., two people were severely injured when a dog ran out from a house situated some distance back from the road and hurled himself directly in front of one of the front wheels of the car, causing the driver to lose control of the steering gear, while the machine swerved sharply and turned over. One of the occupants was thrown clear of the car and the other was pinned beneath it. Both were severely injured, but it is reported they will recover.

Attempting to Pass Another Car.—One man is dead, a young woman is dying in a hospital and two men and two women are suffering from severe bruises at Toledo, O., as the result of the overturning of a touring car when trying to pass another. The six persons were out for a ride and in an attempt to pass another machine went over an embankment, resulting in death and injury as above stated.

Car Skidded.—One man was killed and three injured at Alton, Ill., when the machine skidded and struck a curb, overturning the car. It appears that the driver was making an effort to avoid hitting a dog. The occupants were pinned beneath the car.

Result of Excessive Speed.—What might have been a fatal accident occurred at Ogden, Utah, when three boys returning from the city and driving at the rate of fifty miles per hour failed to calculate the distance and crashed into a hay rack, throwing the driver over the horse's head and the rack into a heap at the horse's heels. Three of the men were taken to the hospital severely injured.

Struck a Soft Spot in the Road.—Two children are dead, the mother will probably die, the father is suffering from a badly injured back, concussion of the brain and a broken shoulder, and two other people severely injured, as the result of an accident which occurred near Eaton, Col. The driver, in attempting to turn a corner, struck a soft spot in the road, and the car was completely overturned, throwing the occupants out.

Riding on Running Board.—At Indianapolis, Ind., a man was crushed between a gate post and an automobile on which he was standing on the running board. When the driver attempted to turn in the gate the man was caught and crushed about the chest and abdomen.

While Cranking His Car.—A man was painfully injured at Plainfield, Ill., when in the act of cranking his car he failed to push the handle on for connection with the shaft of the motor. Throwing his weight on the down stroke the handle went down without the expected resistance and the result was a painful injury to his wrist.

Lost Control of Wheel.—A car going at a moderate rate of speed in Houston, Tex., struck a soft

Digitized by Google

spot in the road, causing the driver to lose control of the wheel. The car reeled off the road, turned turtle three times and then faced in the direction whence the party had come. One man was killed and two women seriously injured.

Gear Lever in "First."—A young man was fatally injured in Chicago, Ill., when in cranking a car it suddenly started forward and crushed him against the front of a truck. It appeared that the gear lever was in first speed.

Collided With Buggy.—While attempting to avoid a collision with a buggy, a man at Pass Christian, Miss., drove into a ditch. The automobile overturned, pinning the driver and his companion beneath. The driver received injuries from which he died shortly after his removal from the car.

Sudden Swerve to Avoid Collision.—A young man was instantly killed and three of his companions injured when traveling at the rate of 35 miles an hour; the sudden appearance of a buggy going in the opposite direction caused the driver to turn to one side so quickly that the wheel of the car ran into the ditch, upsetting the car and turning the occupants out, with the result as stated above.

Driving on Car Tracks.—Two are dead and four injured at Los Angeles, Cal. The party of six started out for a ride when the chauffeur drove on the car tracks before he saw the on-coming car. He made a frantic effort to drive off the track and avoid a collision, but without success. The street car struck the automobile and scattered its occupants, killing two and injuring four.

Car Cleaning.

Cushions should always be slowly dried by the application of a gentle heat. Grease marks from oily fingers will not disappear under hosing, and must not be rubbed off with a wet cloth or removed with kerosene, which is death to varnish; but they come away easily under soap lather, after which the place should be thoroughly flushed with clean water.

Bad spots on coach varnish, due to leaving dry mud on the car for several days, will never yield to hosing or kerosene, but can usually be eliminated with cotton-wool dipped in linseed oil; the same applies to bad rain marks on the bonnet. It is wise to polish up all the coachwork occasionally with one of the special polishes sold for the purpose, which, incidentally, removes most spots and vivifies the varnish. Dusty cars should never be wiped down with a dry cloth; the scratches thus made are ineradicable. A car should never be dried in bright sunlight after a wash down, or the polish will be dulled; notice that many private garages have their washing floors roofed in with opaque material for this reason.

Dusty cushions are best cleaned with a vacuum machine when such is available, otherwise the dirt may be mopped off with a damp cloth; when the latter method is used, the cushions deserve occasional treatment with a leather reviver. Soap, water, and a scrubbing brush are the best treatment for rubber-covered floor and running boards; when aluminum matting is provided, a little turpentine is the best cleanser.

Never take it for granted that the road will be clear when you cannot see right ahead.

REFITTING OLD CARS.

Some Things That May Be Done for Their Improvement.

Just how much it is desirable to expend on a used and out-of-date car to put it in shape for selling or satisfactory service, is a matter that depends much upon circumstances and conditions. It may be desirable to spend more on some cars than on others. Some are more adaptable to improvement and others, owing to structural pecularities, require much time and labor being expended on them to fit, for example, a new carburetor or a magneto. It requires a practical and experienced eye to judge the position as regards making improvements at a reasonable outlay.

It would be difficult, for instance, to justify from an economical standpoint the fitting of a new carburetor if it requires half as much more on fitting it. The same with a magneto. The question of ease of adaptability of a second-hand car to improvements is one that should be carefully taken into account in making a choice of one.

It is not the intention to give directions for fitting a carburetor, as this obviously is a question that would have to be decided on the merits of each case. Every car will require different treatment. Some general remarks on the subject, however, may be given. The chief defects of the older carburetors are heavy consumption of fuel, variability of the mixture and want of flexibility, so that the throttle range is much limited. The large number of carburetors on the market make it a matter of difficulty to decide whether any given type possesses the desired features, although, as a matter of course, each maker considers his particular carburetor as "the best." There are, however, a number of carburetors that might fairly be classed as "standard" types, in view of the fact that most of the well-known cars will be found to have one or other of them fitted. Hence to select one of these is a sound policy. Complication in a carburetor is not a desirable feature, and although extravagant claims may be made for a carburetor that embodies a large number of parts, these claims can be reasonably discounted. The results that any specified carburetor will give, particularly in the case of a second-hand car, cannot be calculated or guessed beforehand; it has to be tested, and it is as well not to expect an immediate big jump in improvement.

Every carburetor requires adjusting to its work and by trial or experiment. If the fitting is done by a concern that has had experience in that line, they can be relied upon to arrange the carburetor to the best advantage. In most cases a new and more efficiently shaped inlet pipe can be fitted, one that will give the mixture an easier flow to the cylinders. Particular care will be taken to keep the carburetor as close to the cylinders as possible, so that it can be maintained at a sufficient heat to ensure the vaporization of the mixture—a most important factor in economical fuel consumption in these days of heavy grades of gasoline. Not less important is it to arrange the carburetor so that it is assured of getting ample "head" of gasoline from the tank when climbing hills, and this may mean effecting a compromise between a short inlet pipe and a long one; this is an even more important re-

Digitized by Google

quirement than keeping the carburetor warm by close contact with the engine.

For working in conjunction with a new carburetor a hand-controlled extra car inlet is an acquisition. A point that should be noted is that it is of such a type that it will actually admit an ample volume of air when required. Some of these devices simply open a quite small aperture that can actually have but little effect. Another point is that great care must be taken to avoid unintentional air leaks. The extra air valve should, therefore, be so well fitted that it can be kept airtight. There must similarly be no air leaks up the inlet valve guides or at any joints between the carburetor and cylinders. Neglect of these precautions is a prolific source of difficulty in getting good results from a new carburetor. An effective control for the throttle is very desirable, and this is rarely found on a second-hand car. Therefore, it certainly pays to remove any existing shaky arrangements of rods and loose connections and install an up-to-date wire control, giving fine gradations of throttle adjustment and avoiding backlash.

Any second-hand car that gives good results with coil and battery ignition may give even better results with magneto ignition. The engine will fire with greater regularity or synchronism; it will be more flexible and responsive to the throttle, and it will have more "life," especially on hills. Furthermore, the batteries being unnecessary, recharging is avoided, and there being no vibrators or contacts to attend to at short intervals the car owner is relieved of a lot of trouble. The whole ignition system is greatly simplified, and a lot of wiring and connecting up dispensed with; in fact, the coil, batteries, wiring, etc., on a second-hand car can be safely regarded as useless or out-of-date. Some there may be who like to make assurance doubly sure and who might care to retain it, but the up-to-date magneto is as "reliable" as anything to which the term can be applied. Moreover, given a well-adjusted carburetor it can be relied on to fire the charge in the first few pulls round of the engine.

Mounting and Driving a Magneto.

It is more satisfactory to have a magneto of the latest pattern, and preferably a new one fitted, rather than to economize by having a cheaper earlier pattern, as, even if in good condition, it is rarely the case that an easy start can be obtained on it owing to the weak initial spark produced. If a more recent pattern can be got it should at least be remagnetized to ensure an efficient starting up spark. The problem of adapting a magneto to a particular car is not always a simple one. Assuming that the engine is a four-cylinder the magneto will have to be positively driven, i. e., by toothed gearing or a chain at the same speed as the crankshaft. At the same time the magneto has to be in an accessible position, so that any adjustment of the contact breaker or distributor can be quickly effected.

Whatever point may be decided upon from which to take the drive, and this varies with every make of engine, a special rigid metal platform will have to be made to support it. This usually means making a pattern and having a casting in aluminum alloy or brass made from it. The best positive drive is by well cut gear wheels, as the accuracy of the timing is more constant.

A chain drive for the magneto is, nevertheless, quite practicable, and many of the older pattern cars are fitted with it. With well cut chain wheels mounted quite truly and a high-quality chain of small pitch, such as a ½-inch pitch bicycle chain, it will not give much trouble. The wear and consequent stretch of the chain will have to be provided for by mounting the magneto on a slotted base, so that as the chain becomes slack the magneto can be set farther back and the correct tension maintained. This question of adjusting the chain from time to time is an important one, as any undue slackness may easily result in the chain jumping the teeth and damaging the magneto or the chain wheels, particularly as the drive tends to be a jerky one, owing to the varying magnetic pull. As the chain will have to be run uncovered, it should be kept lubricated by an occasional application of graphite grease.

The question as to whether "fixed point" timing or variable ignition timing should be adopted should be decided in favor of the latter. Fixed point timing has nothing to recommend it beyond effecting a small amount of simplification by eliminating the ignition control. To obtain the advantage of such control, experience and careful observation of results are necessary, but it is nevertheless worth having.

Wiring and Use of a Switch.

The provision of a switch for the magneto means having an extra wire, and this sometimes is the cause of trouble from occasional short circuits if the wire should happen to get its insulation damaged and touch the metal work adjacent. It sometimes happens also that it is forgotten that the magneto is switched off, and thus considerable effort is wasted at the starting handle. The wiring from the magneto to the plugs should be done neatly and efficiently, which is an easier matter than is the case with coil ignition, as there are only four wires or cables necessary. A vulcanized fibre tube, supported by light metal brackets on top of the cylinders, is as neat an arrangement as any to carry the cables. This tube, of course, is drilled at four places corresponding to the position of the spark plugs, so that each cable can be brought through to connect up.

The Water Circulation System.

The radiator and water circulation system in general on the earlier patterns of cars offers scope for improvement. In most cases these cars are fitted with a pump to provide forced circulation. This detail is likely to be a source of trouble due to leaking or choking up. It becomes, therefore, a matter for consideration whether the system can be converted to the modern thermo-syphon principle. If the radiator is large enough this conversion should not entail anything beyond altering the pipes, so as to give a good flow and return from and to the cylinders. The pipes will have to be much larger in diameter, certainly not less than twice the internal diameter of those originally fitted, and with as short and direct a run as possible. It does not follow that this conversion would be practicable in every case. Even with a new radiator fitted—one designed for thermo-circulation—a sufficient flow could not be obtained, because in this system the position of engine and radiator must bear a definite relation to each other. Thus, if the engine is mounted low in the frame, so that the lowest part of the water jacket is several inches lower than the base of the radiator, an efficient degree of thermo-circulation cannot be

Digitized by Google

obtained. In the case of a car having the radiator under the frame and well below the engine, it would be impossible to obtain a flow without a pump. Cars with this arrangement of radiator are, with one or two exceptions, of a much older pattern than presumably would be considered by a buyer of a second-hand car nowadays. The efficiency of any radiator can be increased by having a fan fitted. With a sufficient clearance available behind the radiator it is a fairly simple matter to fit a fan, the drive being taken from a pulley mounted on the forward extension of the crankshaft.

Increasing the Compression.

The question of increasing the compression of an engine as a means of obtaining more power or a better economy of fuel, is one not easily answered. The fact is that an engine with what could be termed an actual low compression type is rarely met with. On the other hand, many engines have weak compression as the result of leaky valves or piston rings —an easily remediable defect, which a faulty compression ratio is not. Engines designed so far back as 1905 have ratios giving somewhere between 60 lb. and 70 lb. per sq. in., and the touring car engine of to-day does not, as a rule, exceed 75 lb., and some are about 70 lb., as it is found that when these figures are exceeded the disadvantages, such as vibration and tendency to knock when the load becomes heavy, offset any higher efficiency obtained. There is, however, no reason why an engine which proves by test with a compression gauge to be less than 60 lb. should not be brought up to at least 65 lb. by having a set of longer pistons fitted. This plan is likely to prove more satisfactory than having an aluminum plate fitted on top of each piston, mainly owing to the great difficulty of getting the plates permanently fixed. Sooner or later the plates become loose and cause leakage. With some engines a small though sufficient increase of compression can be obtained by having a new set of valve caps made; these being so designed as to screw deeper into the port than the originals, care being taken that there is enough clearance between the bottom of the valve cap and the valve head to allow the latter its full amount of lift.

The question of the advisability of reducing the weight of reciprocating parts as a means of getting a smoother running engine can only be decided by a consideration of the weight of the existing parts. The difficulty that arises is that the reduction in the weight of pistons and connecting rods that can be effected by drilling or cutting away surplus metal is small, as a margin of safety must be left in the parts. Hence it is that so many experiments of this sort fall short of the results expected, and that would be commensurate with the time and labor expended. A much better result can be obtained by having new sets of steel pistons and connecting rods fitted, as, in this way, at least, half the weight of cast iron pistons and old-fashioned mild steel connecting rods can be saved. Here, again, it is a question of the outlay being warranted, and that remains for the owner to decide. There is hardly any limit to the amount of conversion and reconstruction that can be effected on a second-hand car, providing that the outlay be of no consequence. Of course, such conversion might be done in several instalments, particularly when the engine has to undergo an annual overhaul. The outlay thus spread over several seasons' use of the car might thus prove to be the sounder economy than expending a large amount straightaway.

Electric Lighting.

Apart from its high efficiency, the convenience of an electric-lighting set is a matter that every purchaser of a second-hand car should give due consideration to. He may be fortunate enough in being able to buy a car so equipped, but, if not, he can have any car he may buy fitted up with a dynamo set at an outlay ranging from about $75 upwards, the sum in any given instance depending on the class and power of the outfit and the amount of work necessary on the car to install it. There is the mounting of the dynamo, the provision of a driving pulley, mounting platform, the wiring-up and fixing of the switchboard and batteries, and other minor details. Some cars are more easily dealt with than others, particularly as regards driving the dynamo, hence, in some instances, the ratio of the cost of fitting up the set to its original cost may seem high; but it is actually money well laid out if the work be well done, and it means no further outlay. To be able to "light up" by the mere touch of a switch and have control over each lamp is a convenience that only those who have had lengthy experience with the older systems of lighting can fully appreciate. Thus there was the inevitable delay in lighting up, especially on a wet and windy night, the difficulties of getting an acetylene generator started, not to mention the periodical cleaning and recharging of it. Then there was the cleaning and trimming of oil lamps, at best messy and tedious work. All this and more is avoided with an electric lighting set. Nor should the prospective buyer have any doubts as to his ability of managing such a set.

The dynamo is an even less complicated machine than the ignition magneto, and equally as reliable, and electrical knowledge is, as everyone knows, not by any means indispensable to ensure obtaining good results from the magneto. It practically looks after itself, and, similarly, so will a lighting set. This is not to infer that the user of such a set would not find it worth his while to learn all that he can about it. For one thing, it makes a most interesting study to learn the why and wherefore of every part of a lighting set, and it is knowledge, moreover, that can be put to good account sooner or later. But present lack of this knowledge should not in the least deter anyone from having an electric lighting set. The tightening of the dynamo belt, the addition of a little water to the battery, or the replacing of a worn-out bulb in one of the lamps are operations of the simplest non-technical character.

The Metz as a Hill Climber.

From C. A. Sleeper, New Hampshire.—I note in your January number that Mr. Foster takes exception to Mr. Archer's opinion as to the superiority of the Metz car over the Ford, and it is, of course, an open question subject to debate; but it is safe to assume that the man who purchases the Metz car considers that machine superior, and the Ford purchaser doubtless has a similar opinion regarding the Ford.

The question raised, however, is not to compare the two machines from all standpoints, the Glidden tour answering this question, but simply their efficiency as to hill climbing; and when Mr. Foster states that in Arizona a Ford regularly negotiates

---

Digitized by Google

hills impossible to the Metz, he is certainly ignorant of the hill-climbing properties of the Metz as a twenty per cent. grade in Arizona does not differ radically from a twenty per cent. grade in West Virginia, New Hampshire or Australia, and if he doubts the veracity of the statements of owners of Metz cars throughout the country, he may refer to the statements made by the Metz Company which they doubtless would be glad to substantiate with proofs, if necessary, proving that the Metz on hill work can do all that any car with engine of equal horsepower can do—and then some.

Mr. Foster states that the Ford car climbs hills that could not be taken by any car driven by friction. It is always better for one to tell what his make of car can do than what the other fellow's cannot do unless he can furnish the necessary proof, which I doubt if Mr. Foster can; and I am confident that the Metz Company will if asked to.

MAGNETO EFFICIENCY.

In Perfecting Its Details Much Ingenuity Has Been Expended.

It has often caused surprise that so apparently simple a piece of mechanism as a magneto should have taken so many years to develop into a thoroughly reliable machine. It must be remembered that the magneto of to-day is actually the successor of a much simpler type, namely, the low-tension magneto. The reason that this latter type of machine had but a comparatively short existence was not that there was any fault in the machine itself, but because of the fact that it could not be used with an ordinary spark plug, but required a special mechanical arrangement which had to be made as part of the engine, and which was both complicated and liable to failure. If anyone had discovered a means of operating the ordinary form of plug in a direct manner with the low-tension magneto, it is safe to say that the present-day magneto would be non-existent. The construction of an efficient low-tension machine was easy, but, as it proved, the experience gained with it did not avail to any extent in the construction of an equally efficient high-tension magneto to operate an ordinary sparking plug.

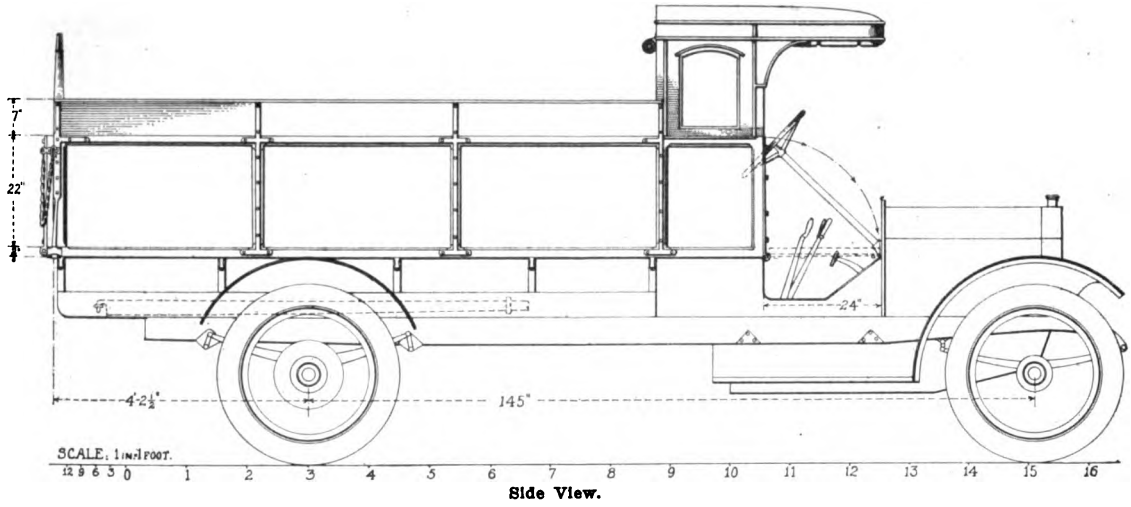
It was soon discovered that an entirely new set of problems had to be solved, problems of a mechanical and electrical nature that required the highest scientific skill to elucidate. Take, for example, the most sensitive part of a magneto, viz., the armature. The efficiency of this very largely depends on the retention of perfect insulation indefinitely and it was in this respect that a great proportion of the early efforts to make a self-contained high-tension magneto failed. A breakdown of the insulation is, in fact, comparable with a burst set of cylinders, as immediate repair is hopeless. The strain on the insulation of a magneto working at normal high speeds is enormous, nevertheless it is a very rare occurrence nowadays for armature insulation to fail.

One of the most troublesome problems of the early magnetos was the provision of a really reliable condenser, a part which probably the average car owner knows very little of, hidden away as it is in the end of the armature. This part also is subjected to a very severe insulation stress. Many of the early magnetos had this part made as a detachable unit, and it was certainly not advisable to go out without a spare condenser. One of the most remarkable achievements of the modern magneto is the excellent manner in which the platinum contacts resist wear and tear. Instead of having to trim them up every 400 miles or so, as was at one time necessary, it is quite usual now to run 2,500 miles without looking at the contacts. This achievement has only been possible because of a practically perfect condenser being fitted.

The chief mechanical part of the magneto, known as the contact make and break, is a most satisfactory device despite the fact that it is subjected to more wear and tear than any other part. In the construction of this part the extremely fine workmanship of the magneto as a whole is exemplified, and undoubtedly if it were not for the fine workmanship such a part could not be relied upon to run the many thousands of miles it does without requiring the renewal of any detail. The application of ball bearings have done much towards making the magneto a perfect machine. These bearings are a comparatively recent innovation, and the use of them has made possible what may be termed the extremely close working of the armature relative to the magneto; the clearance in fact has been made as small as .0005 or half-a-thousandth of an inch, a point which greatly increases the sparking efficiency of the machine, especially at starting. Any failure of the bearings in the shape of wear would, of course, render so fine a clearance an impossibility.

In perfecting the smaller details of the magneto a wealth of ingenuity has been expended. For instance, by various improvements the whole machine has been made waterproof, and this has been a much greater accomplishment than that of only making it dustproof. In the matter of making the connections of the cables that lead to the spark plugs from being awkward and unreliable fitments, it would be difficult now to suggest any further improvement. The provision of efficient lubricators which give access to all bearings is a point that has received much consideration in the design of a magneto, and contributed in some measure to its reliability. One of the troubles of the earlier patterns of machine arose from haphazard oiling. This resulted in oil reaching the contact-breaker surfaces and fouling them, but this is a trouble which is very rarely experienced nowadays. The foregoing will doubtless convey an idea of the various points which in combination have made the magneto so reliable and efficient a machine for the arduous work it has to accomplish. This fact is of particular interest at a time when the question of having to construct magnetos for the home market has to be considered.

Leaky Radiators.



From Dr. S. Harper Smith, Pennsylvania.—Tell "C. H. L.," Connecticut, who asks for "dope" for leaky radiators, there is a reddish colored powder called "Se-ment-ol" made by The Northwestern Chemical Co., that will stop his leaks, and add furthermore that if he prefers he can just get 2 or 3 cents' worth of powdered flaxseed (flaxseed meal) and use that. It will work just as well if it isn't colored red. I've tried both and I know it is not the color nor the scent that does the work.

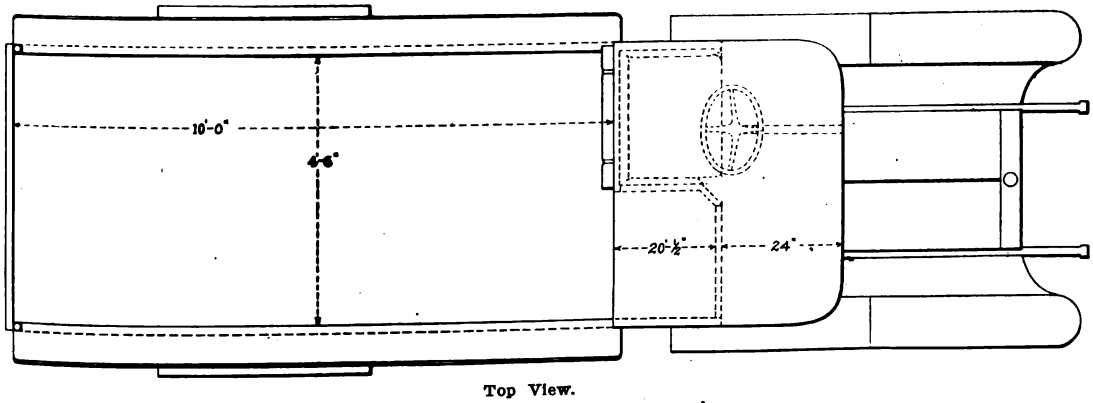
NEW COMMERCIAL BODY.

Maximum Loading Space and Handy for All Kinds of Traffic.

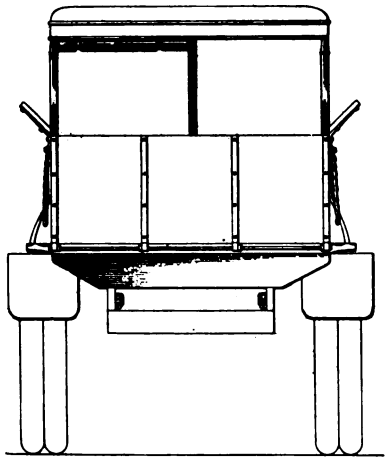


It is the axiom of good business management to get from an investment in a motor vehicle for commercial purposes, the maximum in return, and any change or addition in the body design that makes the vehicle more comprehensive as a general utility proposition is sure to be given due consideration. The motor vehicle is a machine that should be made to deliver automatically up to the limit of its possibilities, so as to properly satisfy the investment of the capital, and provided that the car is right and has the required horsepower for the work, the question of its properly doing its full duty depends largely on whether the body is made to suit the business for which the vehicle is intended to be used.

Side View.

The body here presented has one advantage over the average. This feature is not entirely new, but has been used to a limited extent for suburban traffic, yet it is surprising that it has not been more generally adopted. The idea is to use the space beside the driver for the loading purposes and to permit the taking off and on of the load from the front; that is those articles comprising the load that will so permit of being handled at this end. Ordinarily only one man is needed to handle a car and the most of the time the space beside the driver is wasted. The commercial car carries the gasoline tank under the seat and when the body is narrow and sets down on the frame this plan could not be considered. In the design illustrated, however, the body is above the wheels for clearance and therefore there is ample space for the tank and still carry out the plan as outlined above.

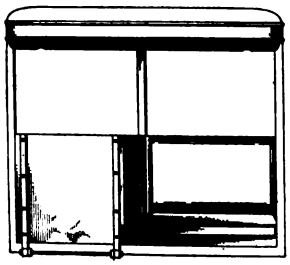
The average body has carrying space back of the seat only. In this design we propose to show how sensible it is to use every inch of space for the load not needed for the driver and in cases where lengths of pipe or lumber are carried, this arrangement is very satisfactory. The several views here shown clearly illustrate how this is accomplished. The space back of the seat is 10 feet long by 4 feet 6 inches wide by 22 inches high to the top of the sides and an additional 7 inches to the top of the flare boards. The overhang of the body back of the center of the rear wheel is 4 feet 2½ inches and this makes more than three-fourths of the load on the rear wheels, therefore it is an advantage to add to the load at the front end, and by the arrangement herein devised the additional space gained is equal to 1/12 of the space back of the seat and if the front tailboard is let down as shown in dotted lines



Top View.

Digitized by Google

on the side view, the additional space gained will equal more than 1/6 of the total space back of the seat.



The body is designed for carrying hay, grain and feed, or it is suitable for plumbing supplies or trucking, the free space from the rear to the dash being especially adapted for lengths of pipe, etc. As a rule these bodies are not provided with a top for the driver, but the idea of a driver's cab suggested it-

End Perspective.

self because it is easier to incorporate the feature mentioned and still preserve the appearance of a body as it ordinarily looks, and then again the furnishing of proper protection for the driver is along sensible lines, especially for long hauls.

The driver is on the left side, and ample room is conserved for one man's comfort. The partition surrounding this seat on the side and the back are the height of the body. Side and drop curtains are

End Perspective.

used at the rear in addition to the regular curtains on the sides and the front. The shift levers are in the center and by looking at the plan view it will be noted that a corner has been lopped off the front of the middle wall to allow free arm movement for the operator when shifting the gears, and the tailboard, which is provided for the front end of the body, is continued only to the angle line, and therefore when it is lowered it is narrow enough to clear the lever handles and allow of them being operated when the board is down. This tailboard is not provided with chains like the rear but is fastened when up by hooks. The idea of letting the tailboard down is not only to allow lengths of pipe or lumber to extend forward up to the dash, but it will also serve as a loading platform. It seems reasonable if light delivery bodies are all made so that the packages can be taken from the front that this rule will also apply to bodies that carry heavier merchandise.

This board is fitted with strong hinges, and as the body is wide the tailboard when down will extend out over the runboards and therefore the person lifting can move directly up to the platform. Moreover, this front loading has the advantage that it is less in height for the lift, because the person stands on the sidewalk while the truck is on the road, and then again the man does not have to go into the muddy road so often as ordinarily, and anything that saves a man's strength promotes his efficiency. It is this line of reasoning that has made more general the adoption of the truck with the motor in front in place of under the seat, because the driver does not have to climb so high. The motor in front can have more flexible springs and the shock to the motor parts is less than with the motor under the seat, but consideration for the man has also been a factor in bringing about this general change.

The body is fitted to a 1½ ton chassis, having 145 inch wheel base and the tires are pneumatic, front 36 inch by 4½ inch, and rear are dual of the same dimensions. The body is built in one piece from the sill line up, and including the cab. It is set 5½ inches above the rear wheels for clearance and this will allow of a 11¾ inch high under body at the front which will permit of a gasoline tank of 12 gallons capacity.

WELL WORTH NOTING.

Piston Rings and Compression Leakage and Spark Plug Troubles.

BY JAMES F. HOBART, M. E.

You can't get full power from an engine with leaky piston rings, and I don't believe you can find one in one thousand but what leaks more or less. It is practically a physical impossibility to make and fit a piston ring which won't leak at all. You can make 'em which are pretty tight and leak but very little, but never yet have I seen one which would hold compression without losing it gradually. To be sure you can grind the cylinders pretty smooth and you can fit the rings to the ground cylinders by more grinding so there is a mighty snug fit between them, but you can't stop all the leakage for any length of time even with double rings where one part covers most of the leakage through the cut in the other part of the ring.

From the very nature of the piston ring, it is bound to leak more and more with wear, and the closer it becomes fitted to the cylinder and the less leakage exists there, the more leakage there will be past the cut ends of the ring. When the ring is new, it should have been fitted so the ends practically touch each other when hot, but if you fit the rings too close together endwise, so the expansion of the ring throws its ends together, then the ring will wedge itself together endwise, sieze the cylinder, and if it don't score or cut, it will wedge so tightly as to require half the engine power to push the tight ring back and forth. I have seen cases

Digitized by Google

where it required more than all the engine power to do that trick, and the engine stopped dead and we had to drive the rings out and polish up the inside of the cylinders again.

The more the rings wear the farther apart the cut ends must be and the more leakage space past them. This makes the engine lose compression slightly but steadily all the time after a set of rings have been fitted. The ring leakage past the cut ends is practically the same in a very small cylinder as in a medium sized one, but the percentage of volume leakage is very much less in the medium than in the small cylinder, therefore the large cylinder loses much less compression through ring-end leakage than is lost in the small cylinder.

The fast running engine has a great advantage over the slow moving one in the way of piston ring leakage also and the engine which makes 1,000 strokes per minute loses less than one-half as much compression through ring leakage as the same engine when making only 500 strokes per minute.

Therefore, select the large bore cylinder and the short, high rotative speed stroke engine and you will minimize piston ring compression losses. Remember that there can be high piston speed without having high rotative speed. The long stroke with slow crank-shaft speed may give greater piston speed than the short stroke engine which revolves much faster than the slow moving one, but this is not the kind of high piston speed which is wanted to save compression leakage. With a given leakage, the quicker the compression stroke is made the less leakage loss, and this is where the economy of the short stroke, high rotative speed engine comes in. The compression stroke is made so quickly that little of the compression has time to leak past the ends of the piston rings. That's all there is to it, and that's the reason why the large bore, high rotative speed engine "has it all over" the other kinds for economy as far as leakage is concerned.

Spark Plug Troubles.

There is another considerable source of compression loss in a good many engines, and that loss is through spark plug leakage. Many a time have I seen a man remove dirty spark plugs, take them to pieces and clean them carefully with gasoline and work off all the carbon deposit. Then, he would carefully oil the plug, screw it together, oil the threads with a little cylinder oil, and screw the plug into the cylinder. I like to listen at that plug as he cranks the engine, and in nine times out of ten, I can hear the compression—or what should have been compression—pushing its way out of the cylinder past the badly fitting spark plug. If the man cannot hear the escape of gas, then just mix up a dish of soap and water—just the same as if you were going to blow soap bubbles. Then, with a clean brush, paint all over and around the spark plug with the soap-suds, and set a man to cranking the engine while you watch the soaped spark plug. If there be the least leakage, in, around or through that plug, the issuing gas will blow up a whole swarm of small bubbles which tell just where and how much the leakage is and your man can see for himself in a manner which admits of no doubting or dodging the returns.

The Soap-Suds Test.

Testing with soap-suds is not only good for spark plugs which are suspected of leakage, but the test is also first class for cylinder ends, induction and exhaust valves and for whatever other gas joints may be found in and around the engine which are subject to compression pressure. Just spread the soap-suds over the parts, crank up compression as slowly as you can and hold it as long as you can, and the bubbles will "give away" any leakage which may exist in the engine.

The soap-suds method is also a mighty good one for testing any piping which you may have made up for gasoline or for air-handling purposes. Just close one end of the pipe, either by attaching a valve temporarily, or by plugging it. Attach the tire pump or a hose from an air tank to the other end of the pipe to be tested. Apply a liberal coating of soap-suds and turn a little air into the pipe, and if there be the slightest leakage in any of the connections—well, the air-bubbles will tell the story at once and also locate the leak with exactness.

The same test may be applied to a gasoline storage tank, but be very careful with the air and do not let in more than a few pounds pressure or you may distort the tank, rip off some of the stays or otherwise tear things up the back. Only a pound or two pressure should be put into a flat gasoline tank for leak testing purposes for there is danger of serious trouble if greater pressure be used. A pound of air pressure will blow a mighty big lot of bubbles through a very small opening, so go slow with the air pressure when testing tanks for leakage. You may use all the pressure you wish on pipes or cylinder connections, and there is no danger from excess pressure, but go very slow when it comes to the testing of tanks—especially of tanks with one or more flat sides or ends. Such flat sides won't stand much pressure without being forced out of shape and perhaps made to leak badly in more places than one.

That Sooty Spark Plug.

But to come back to spark plugs again. The plug which leaks gas is not the only plug defect that must be contended with. There are many plugs which leak electricity almost as fast as a sieve will leak water. I find it does not pay to bother with a plug of this kind. It may be possible to make it electricity-tight, but once a plug gets to leaking better throw that plug aside and put in a new one. When a plug of this kind gets a little dirty, the spark will crawl all around and over the plug, in fact, the discharge will take place anywhere and everywhere except between the proper points. Then there is another plug which belongs to the scrap box, and that plug is the one with many very fine cracks all through the porcelain part of the tube, and when you watch the discharge, you will see it sneak through one or more of those little cracks—anywhere, in fact, save through the proper spark points of the plug. When I see a man wrestling with one of this type of plug, I say to myself, "too much gasoline." He is and has been using too rich a mixture. A plug will not become covered with carbon unless the mixture is too rich, or there is imperfect combustion of the charge from some other reason.

You can usually tell pretty closely, what has been going on in a cylinder by simply unscrewing a spark plug and taking a look at the inner end of the plug. When the plug comes out covered with black soot, or streaked with oil or gasoline, you may be mighty sure that too much gasoline is used in that cylinder, and that things would be vastly improved, at once

Digitized by Google

and permanently by cutting down the gasoline supply.

But when the inner end of a plug looks as though it had come from the inside of a furnace heated to 1,000 to 2,000 degrees, with never a sign of soot or oil on it—then you may be sure that there is good combustion habitually taking place inside the cylinder that plug came from, and that the gasoline and lubricating oil supply is not excessive.

Some Cylinders Skipped.

Only a few days ago, right in front of the office window, a drummer stood over his Ford machine, trying to find which cylinder was missing. He would take out a plug, look it over and wipe off soot as best he could, then he would try another plug and remove and examine that one also. Then he would run the engine slowly for a few seconds, then open up and spin the engine fast, while black smoke rolled out of the exhaust pipe in clouds. He kept this performance up for ten or fifteen minutes, trying first one plug, then another and then spinning the engine again.

Why will a man be guilty of foolishness of this kind? Why will he sit and spin an engine with an over-rich mixture, while the spark plugs are coating with carbon and refusing to function properly? It is hard to understand why men will do this, but they do, time after time, and when the mixture is already so rich that it can't burn, they will shake out another reef from the carburetor, or squirt an extra dose of gasoline into a cylinder, trying to cure indigestion by over-eating! Queer way that of making a cure. No wonder it won't work, but it is a great wonder to me that men with seemingly common sense in other things, will stuff an automobile engine cylinder with gasoline when it is already overfed with gas and can't ignite or burn the charge because there is not enough oxygen in the charge to combine with the amount of gasoline present.

After fooling with his machine as above, for about fifteen minutes, and just as he was about to drive along with cylinders missing occasionally, another machine came along and stopped behind the one in trouble. A few seconds' talk between the drivers of the two machines, and they both went to removing and cleaning spark plugs. The second driver got into the first machine and adjusted the gasoline and turned the engine over a few times before he put the spark on. Then he turned on the juice, gave the crank a single quarter turn, and pu-r-r-r, went the engine, with never a miss and with no black smoke trailing behind. The little machine went off in style, running as well as any machine ever ran, with each and every cylinder working full time.

Why can't drivers of automobiles get it into their heads that most spark troubles come directly or indirectly from too much gasoline? And why can't they remember to cut down the gasoline supply when they have spark plug troubles, instead of increasing the gasoline when it is already too much in evidence? I don't know why they all do this, but they do, nine times out of ten. And I presume that drummer will do the same thing in a day or a week, and then wonder why he has spark plug troubles again.

Recording License and Engine Numbers.

Can you tell off-hand, the number of your automobile license, the number stamped on the engine, also the body number, and the number of the transmission, if that has any number? If you can, you will do better than a majority of automobile users. A good many of them cannot tell even their license number, and if they want the engine number, they may have it recorded or they may not—usually the latter.

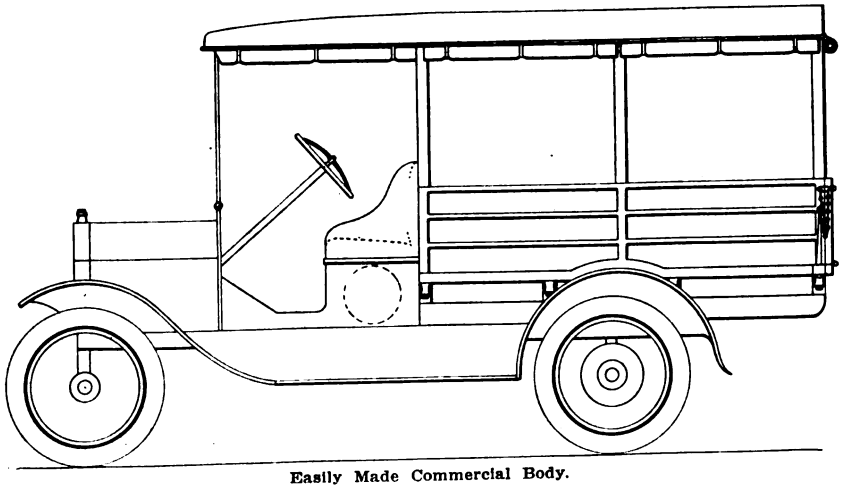
A case happened right here in Indianapolis, on the 27th of February of this year. A gentleman had a little "Tin Lizzie" and drove it to market, purchased a lot of groceries and placed them aboard, together with his box of carpenter's tools. They drove downtown and stopped in front of the Union Station for a few minutes, removing the plug from the ignition circuit, but not locking the machine in any way.

Ten minutes later, when they came back, the machine was gone, and they saw nothing more of it Saturday night or Sunday. They reported the matter to the police, but were unable to give the license number but after making a trip home by trolley, the owner was able to produce the engine number. Nothing was heard from the missing machine until Tuesday morning, while, as they were going to work, the owner and his friend saw a machine with a double tire, standing at the curb, a machine which resembled theirs very closely. They looked the machine over and decided it was theirs. The chassis was nicely covered with a blanket and the drip under the machine, indicated that it had stood there all night.

They phoned to the police station, and were advised, if they thought the machine theirs, to drive it to the station. This they did, and upon investigation, it was found that their engine number was stamped upon the engine. The machine was in perfect order, as good as when it was taken, but the groceries and the tools were gone, and they have staid gone ever since. The speedometer showed that the machine had been run about 500 miles during the time it was gone.

As professional automobile thieves make a point of at once changing the license and engine numbers, together with any other numbers they may find, it stands well for any automobile owner to establish private marks or numbers and stamp them upon some accessible but out of sight portion of the car for use in case of a change of number as above mentioned.

Furthermore, it is a pity that automobile thieves cannot be served with the "wild and wooly West" cure for horse stealing. If an automobile thief knew with certainty that he would be strung up at once when caught, there would not be one automobile stolen where twenty are taken now. Evidently the lamp post cure would be almost a sure one against automobile stealing.



License Fees Cut in Half.

From C. H. Billings, New York.—Referring to your answer to F. M. Groth, N. Y., in the March number, would refer you to Chapter 491, "An Act to amend the Highway Law, in relation to motor vehicles," Sec. 6: "Provided that if a motor vehicle other than one used solely for commercial purposes shall have been licensed for four separate years hereunder and for which there shall have been paid the annual registration fees herein provided during said period, the annual registration fees thereafter shall be one-half the amount."

A Good Commercial Body.

This design of body is for express, parcel and light delivery service. For this purpose two considerations are of prime importance. The driver's seat must be convenient of access and the contents of the fore part of the body must be within easy reach from the driver's seat. To gain these results the seat must be placed as low as possible, this being essential in a body of the sidewalk delivery type. In the illustration it is shown mounted on a standard Ford chassis with a wheel base of 100 inches. With a body of this length, on such a small wheelbase, it is necessary to bring the seat forward about 20 inches from the dash. From the floor to the top of the seat cushion is about 14 inches; from the front of the cushion to the back of the seat is 15 inches. The length of the body back of the driver's seat is 6 feet, 6 inches; the width of the body is 5 feet; the height of the body is 4 feet, 3 inches; the sides of the body are 18 inches high. This body has roll curtains and a hinged tail board, and it is also necessary to use a wood frame built on the chassis to support the overhang of the body, as the chassis frame on a Ford ends at the center of the rear wheels. This will be found to be a very useful body and easily constructed.

Easily Made Commercial Body.

THE FIT OF PISTONS.

A Paper by E. W. Weaver Before the Society of Automobile Engineers.

As the satisfactory running of an engine depends upon the correct functioning of all the different parts, it is improper to single out any particular point as the most important part of the engine. However, the piston being the part first affected by the impulse of the explosion, friction at this point cuts into the efficiency of the engine to a greater extent proportionately than at any point further along the line. It is, therefore, of prime importance that its fit in the cylinder be the best obtainable—sufficiently free to allow for the necessary oil film and for slight distortions in shape under heat, and close enough to prevent "piston slap."

The question of the fit of the piston in the cylinder is not that of a solid plunger operating in a cylinder of heavy enough body and surrounded by such conditions as to insure an unchanging form, and permitting of copious lubrication. The problem is that of a comparatively delicate piston working in a cylinder the walls of which are thin as the designer dares make them and which is subject to great variations of temperature at different points. Lubrication, too, must be held down to the minimum in order to conform to various smoke ordinances, or lacking such inducements, to one's own sense of the fitness of things.

The question of the ideal allowance to make will be considered apart from that of manufacturing tolerances. Some engineers use the very convenient rule of making the piston .001 small for each inch of diameter of the cylinder bore. I believe that the following rule comes closer to actual requirements: Allow from .002 to .0025 for each inch of diameter above two inches.

As it is impossible to manufacture commercially parts that are all exactly alike, due allowance must be made for variations. The engine builder has the choice of the following three methods: (1) putting limits on the drawing and holding the inspection to such a point that any piston will work in any cylinder; (2) sorting the cylinders and pistons according to size, and assembling the large pistons in the large cylinders, etc.; (3) making all the pistons a closer fit than they are expected to run and lapping them down to the proper fit, each in its own cylinder.

I shall touch on the first method only, that of strictly interchangeable production. The fixing of the limits to which the shop is to work is very important, as it affects directly the cost of the product. My idea is that the drawing should represent what the engineer expects, what the shop will guarantee, and what the company is willing to pay for.

Considering the cylinder first, a permitted variation between maximum and minimum size of .0015 is absolutely necessary—.002 is the ordinary allowance—and the cylinder must not be tapered or be "out of round" to in any wise exceed the given allowance.

A variation of .001 between the maximum and minimum for the piston is the usual allowance. If wider limits are given, more care must be exercised in assembling, or the quality of the engine will be lowered.

The head of the piston, being exposed to the

Digitized by Google

intense heat of the explosion, must be made considerably smaller than the skirt. The amount is usually fixed at from .002 to .0025 small for each inch in diameter.

The fit of the piston ring in the groove is another particular point. The rings must be loose enough to operate freely and close enough to prevent gas from leaking past. The minimum allowance that is safe is .0005, and the tolerances on both ring and groove must be given in such a way that this allowance is not diminished. The closest limits that are being worked to commercially are .0005 variation between the minimum and maximum of both ring and groove width.

Allowance must be made between the ends of the piston ring for expansion under heat. From .006 to .015 is the usual amount allowed.

The fit of the piston-pin in the piston is the final point at which great care must be exercised, the proper allowance for the fit being .001 of an inch. The hole in the piston being reamed or broached can be held from exact size to .0005 under size. In the case of a one-inch piston-pin, the hole in the piston would be dimensioned from 1.000 to .9995, while the piston pin would be given as .9990 to .9985, thus insuring a minimum allowance of .0005 and a maximum allowance of .0015.

A company making a specialty of the manufacture of pistons and cylinders is acutely aware of the advantage to be gained by having an accepted standard for the nominal sizes of cylinder bore. For instance, with a nominal diameter, of four inches, one engine-maker may give tolerances of +or—.001; another maker may give tolerances of +0, —.002; and there are various other combinations. This, of course, necessitates carrying special tools and gauges for each size which is made.

It should be stated in conclusion that the suggestions in this paper apply particularly to water-cooled engines, the writer not having had sufficient experience with air-cooled engines to offer any suggestions along those lines.

A SUMMER TRIP.

Suggestions for Car Owners Who Have Never Tasted the Pleasures of an Outing.

From J. F. Shaw, Wisconsin.—I have been wondering whether or not your eastern readers would be interested in a brief account of an August automobile trip along the upper reaches of the Mississippi. Nothing sensational I assure you and perhaps hardly worth the perusal and yet a little outing replete with kindly reminiscence for myself and family.

Leaving Minneapolis on Washington Avenue the route followed an excellent highway to Anoka and Elk River, thence paralleling the Northern Pacific track through a beautiful farming country taking in St. Cloud, Little Falls and Brainerd, all charming and prosperous Minnesota cities. The blazed trail placed by kindly disposed motorists who had preceded us was a welcome beacon which helped us over many a stretch of indifferent highway and around some lonesome corners. By the way the "trail" helpful as it is, follows the wrong side of the river between St. Cloud and Little Falls. On the return trip, leaving the trail at Royalton we bore to the left and soon came to an abandoned Northern Pacific right of way where we had the pleasure of riding many miles on a water-level, cindered roadway. This was worth finding and leads me to the observation the blazed trail is sometimes subject to modification in a new country.

Though approaching its northern environs the Mississippi still presents a lordly aspect through this section. It seems a thing of life, proudly conscious of the important part it plays in the welfare of the vast region it traverses. Its spacious banks abound in attractive camping places where the eye is charmed with delightful vistas of land and water scenery. I will never forget the pleasant lunch hour on the river bank where we wasted time scandalously, skipping stones, wading, visiting and idling. Did I say "wasted?" Quite the contrary after all. Time spent in the society of your own family in the big out-doors is never wasted.

Numerous trains passed us en route and we always got a friendly wave from the fireman. Passengers would frequently beckon us to come on but inequalities in the roadway would soon render a slowdown justifiable if not imperative in the interest of "safety first," so we invariably suffered defeat. But it was some fun to try.

Some eight or ten miles south of Brainerd we came to a splendid piece of permanent road constructed of iron slag. This lasts until within a mile of the city, the balance of the way being over sand interspersed with jack pine roots. I dare say this iron highway will be connected up with Brainerd's excellent macadam system in the near future.

After a week's vacation at Brainerd, Marse Ford declined to start at six o'clock in the morning for the return trip. The insertion of one new spark plug, however, remedied the difficulty and we were soon bowling merrily along through a succession of mud holes occasioned by a heavy rainfall of the previous night. A two hours' ride in the warm, moist air of early morning found us in capital shape to enjoy a bountiful open air breakfast provided by friends at International Falls. We stopped near the shore of a little lake on the opposite side of which a number of tepes bespoke the probable presence of a band of Indians, mild and peaceful descendants of the proud warriors who once roamed this region.

With reference to vegetation we were on the dividing line, the various evergreen growths giving way to the oak family, these in turn to be superseded as we journeyed southward by the big elm, maple and basswood with which we are familiar in Wisconsin. Characteristic vines clustered the adjoining hedge and the slender hazel gave timid evidence of later fruitage; the sumac claimed attention through the conspicuous wizardry of early frost.

Breakfast over we hustled along without special incident enjoying every moment of the ride. A pretty park and an adjacent cold spring helped us while away our rest hour at St. Cloud. Toward evening the one blow-out of the trip occurred inopportunely (was ever a blow-out opportune?) and the consequent delay made the brilliant illuminations of Hennepin Avenue, Minneapolis, doubly attractive through the promise of restaurants galore.

The Twin Cities are replete with attractive drives for the motorist. Minnehaha Park, Minneapolis, is the Mecca for thousands of auto parties, picnic bent. from all over the northwest. Lake Harriet and Lake of the Isles drives are unsurpassed for beauty. Riverside Drive, for pleasure driving exclusively, follows the high banks of the river between the two

Digitized by Google

cities and includes historic Fort Snelling and other points of interest. Thence down Summit Avenue, St. Paul, said to be one of the handsomest streets in the world. Tourists traversing St. Paul should not miss Como and Indian Mounds Parks.

Leaving St. Paul on East Seventh Street, the friendly blazed trail leads the way along the river southward through St. Paul Park, Hastings, Red Wing and Lake City. Between the latter named towns the celebrated Lake Pepin may be seen nestling at the foot of the Wisconsin bluffs. The scenery in this locality is truly of surpassing loveliness. The lake lies like an emerald, reflecting every passing shadow, its surface sparkling in the sunshine or in turn dark and frowning as storm clouds skud above it; for the little lake with all its charm and beauty is also treacherous and on many a sad occasion has taken toll of human life. The locality abounds in Indian legend and romance, the very names as Red Wing, Waucouta, Frontenac, Maiden Rock, etc., indicating their origin and here the lover of Indian tradition can unearth enough to fill a volume. Here in this land of romance lying so peacefully in the warmth of August sunshine we must resist the beckoning call of the majestic river and reluctantly leaving the friendly sign of the blazed trail we wend our way across the bluffs to the good, old Wisconsin home, each and all the better for our little outing and looking forward with pleasant anticipation toward the next opportunity for a similar trip.

MOTOR AMBULANCES.

A Prize Competition and a New Body Design by Hale & Kilbern Co., Chicago, Ill.

The motor ambulance has attained a good deal of prominence since the great European war and it is now being extensively used. Experts have already begun to study the matter to find out if something may not be done to improve the present type. Moreover, in England, at the instance of Mr. Henry S. Wellcome, the founder of the Wellcome Bureau of Scientific Research, a commission has been formed, and the names of members show at once that the matter is regarded as of first importance by those most intimately connected with the welfare of the wounded soldier. This commission will first act as a judging committee for the award of prizes of the value of £2000 provided by the Wellcome Bureau of Scientific Research. These prizes are offered for the best designs of ambulance body which shall fit a standard pattern motor chassis for field motor-ambulances. The last day for the receipt of completing designs is June 30, 1915. It is hoped that the competition will bring in a number of ingenious designs, from which the ideal field ambulance-body will be evolved.

The sum of two thousand pounds will be divided into a first prize of £1000, a second prize of £500, a third prize of £300, and the remaining £200 will be awarded in smaller sums.

The first, second and third prizes are for a complete design of an ambulance-body, complying with the conditions hereinafter laid down. The Commission reserves the right to award the whole or any part of the remaining £200 for details, such as an ingenious method of springing, an invention which could be applied to any motor-chassis, an ingenious method of storing arms and equipment, a novel system of lighting, mechanical devices for self-haulage, etc.

Among the conditions relating to construction are that the ambulance must carry four patients; the driver and orderly must be provided with shelter; the vehicle must be capable of being loaded from the ground by four or less bearers; the center of gravity of the body must be low; and the material of the body must be as non-inflammable as possible. There are other requirements which will naturally be borne in mind by those who compete.

In this connection, a body design is presented herewith which of course was outlined and completed before this competition was published, the builders being the Hale & Kilburn Co., Chicago, Ill.

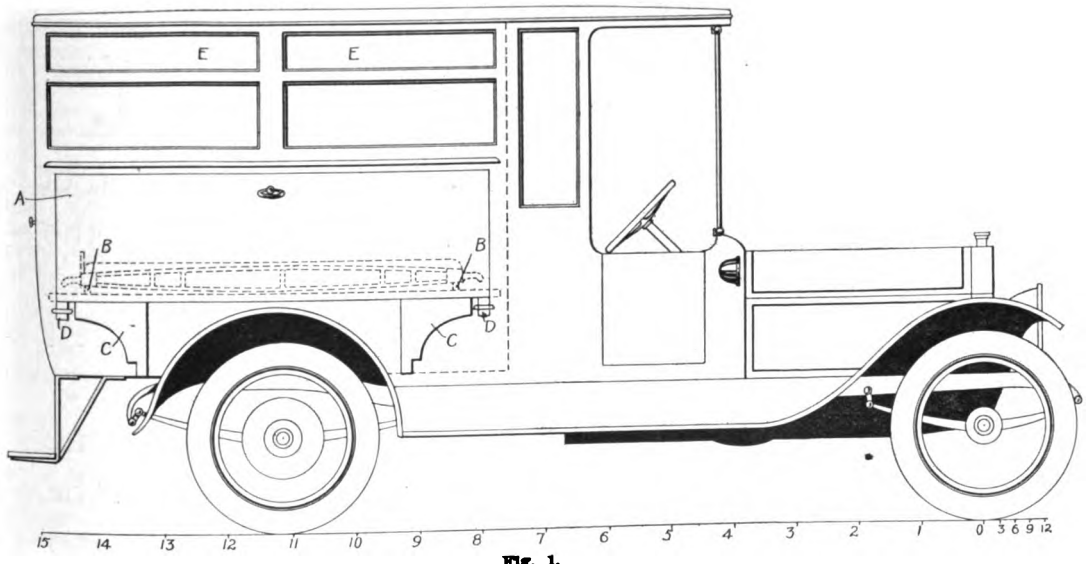

Fig. 1.

This body is built entirely of steel, there being no wood used in its construction. It is shown mounted on a Pierce-Arrow chassis. Even the stretcher is of steel. The novel and highly convenient method of access for injured persons will be noted. The side panel A, shown in Fig. 1, falls

Digitized by Google

outward, allowing the stretcher to be run out on a pair of runners B, shown in Fig. 1, and Fig. 3, for enabling the patient to be deposited on it with greater ease than is possible when access is made use of by the rear and in other types of bodies. The body also has two brackets C, which are hinged to the side of the body in such a way that they can be swung outward to support the panel when open. There are also two sliding brackets D, which are pulled out of a recess, to also help in the support of the panel. In Fig. 2, I have shown a window next to the driver, for means of giving light into the body, as well as from the sides and rear. There are two ventilators over the side windows marked E, in Fig. 1. This design is conveniently constructed in many ways and one of its advantages is that it is unnecessary to back to the curb but is drawn up lengthwise with the curb, therefore, not interfering with traffic, as the ambulance bodies of the past, but allows other vehicles to pass conveniently.

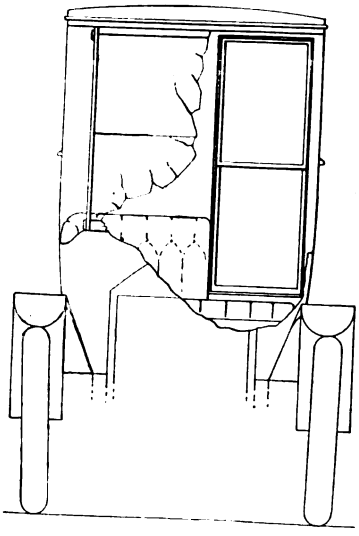

Fig. 2.

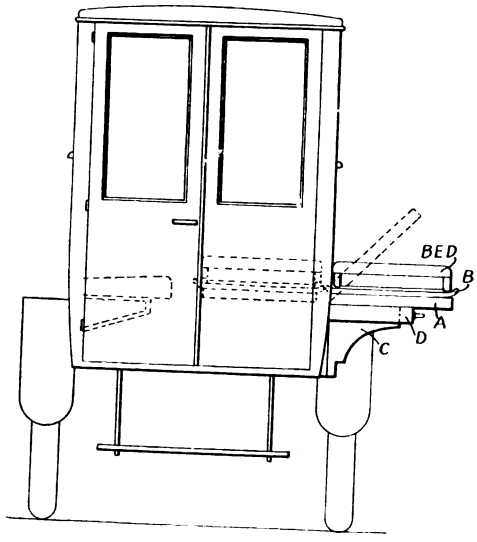

Fig. 3.

ONE STROKE OF A BELL

in a thick fog does not give any lasting impression of its location, and if it were not followed by others the vessel might strike the rock. But repeated strokes at regular intervals, even in the densest fog or the darkest night, will soon make its exact location absolutely sure. It is absolutely the same with advertising; one insertion hardly makes a sufficient impression on the mind of the possible purchaser, and if faint of sound it might about as well not have been inserted at all. But constantly repeated, it will soon make an impression that cannot be forgotten.

NEW AND INTERESTING THINGS IN MOTORDOM

Korine Carbon Remover.

This is a preparation for removing carbon from motor cylinders. The manufacturers state that it contains no acid, grit or chemicals and it will do the work thoroughly and quickly. This is an especially attractive proposition for dealers, and any who may be interested should write for full particulars to the Korine Carbon Remover Company, 136 Federal Street, Boston, Mass.

Price Was Incorrectly Stated.

In the March number of the Automobile Dealer and Repairer, we published in this department a description of the Stream Line Hood for Ford cars, manufactured by the Superior Lamp Manufacturing Company, 136 West 52nd Street, New York City, and the price of this hood was erroneously quoted at $11.40. The correct price of this hood is only $8.00, as it was stated in the advertisement appearing from this company, in the same issue.

Special Wheels for Ford Cars.

A line of special wheels and demountable rims for Ford cars, also automobile wood wheels of all kinds is manufactured by the Meeker Manufacturing Company of Dayton, Ohio (Station A). They will be pleased to furnish best estimates and full particulars to all readers who will take the trouble to write to them, and prompt deliveries are guaranteed.

The Ideal Oil Gauge.

This is a thoroughly practical oil gauge especially designed for the Ford car. It is attached right on the dash in plain sight and it is accurate and reliable. It has the enthusiastic endorsement of thousands of Ford owners now using it. It is simple, inexpensive and there is nothing to break or get out of order. Can be attached in five minutes by anybody, and it is made to fit exactly. It is an especially good proposition for jobbers and dealers. Any who are interested should write to the manufacturers, A. B. Worthington, 1220 San Pedro Street, Los Angeles, Calif.

Double Tread Tires.

B. Liben & Co., 261 West 54th Street, New York City, are manufacturing what they call the Double Tread Tires, and they state that this tire is made of 12 layers of fabric and one-inch of solid rubber. It is further stated that this combination makes a tire of great strength, and it is also claimed that this tire has greater resiliency than the ordinary shoe. It is also guaranteed to be absolutely puncture-proof and it is claimed that a stone bruise has no effect whatever on this tire. Readers who will take the trouble to write this firm will be given full particulars, prices, etc.

Enlarging Their Plant.

On account of the rapid increase in business of the Connecticut Telephone & Electric Company, it has been necessary to make an extension to their plant by another addition approximately 50 x 100 feet. This building when completed will have four floors and a basement, and will be of modern brick mill construction with all up-to-date appliances. This building will be completed for occupancy by April 15th, and will be largely devoted to the manufacture of Connecticut Automatic Igniter Systems. This makes the third modern extension to their plant within the last few years.

Bethlehem Spark Plugs for Racing.

Johnny Aitken, the well-known driver of National cars, has used Bethlehem Spark Plugs and he has highly commended them in a written testimonial, stating that in his judgment they are the best plugs on the market. Of course the test to which a driver like Aitken puts his spark plugs are unusually severe and the fact that the Bethlehem stands right up under every one of these tests is evidence of the sturdy construction and mechanical merit of the plug. This plug is manufactured as most of our readers know by the Silver Company with a main office at 171 Madison Avenue, New York City.

Armstrong Stocks and Dies.

A very complete line of stock and dies for cutting A. L. A. M. treads is manufactured by The Armstrong Manufacturing Company, 335 Knowlton Street, Bridgeport, Conn. The dies are adjustable, and as tools of this character are practically indispensable in repair shops many of our readers are likely to be interested in them. Correspondence direct with the manufacturer is invited.

The Witherbee Storage Battery.

The manufacturers of this well known battery claim that it will stand up in ignition, illumination, and starting service under the most trying conditions, and they also state that it is a conservatively rated battery. This battery is backed by over 10 years practical experience which should be in itself a guarantee of reliability. Readers who are interested should address the Meder-Staudt Company, Inc., 1876 Broadway, New York City. This company also specializes in the repair and exchange of batteries of any manufacture, and they carry complete facilities for this work both in New York City and at their factory in Springfield, Mass.

Will Protect the Public.

At the first meeting of the Directors of the United Garage Association of New York State, Inc., held at Albany, it was announced that detectives had been retained to search out dishonest garage proprietors and assist the association in exposing them and their methods and protecting the public.

The Carburette Vaporizer.

The manufacturers of this new device state that it enables the driver to throttle a Ford car down to four miles per hour, and also get away quicker and with a degree of smoothness which would not be possible without it. This device is designed to fasten neatly to the exhaust pipe, just back of the dash, with suitable means for connecting the gasoline pipe leading from the tank, and connecting the broken end from the carburetor. The gasoline passing through the Carburette becomes heated and also clean of any dirt, water or sediment, and it is claimed that the heating of the gasoline causes more complete carburetion. The warm gasoline coming in contact with the air attains a finer degree of vaporization making far more power, flexibility and smoothness of the motor, and it is also claimed that with the Carburette Vaporizer, the needle valve can be closed about ¼ of a turn, allowing a saving in gasoline of 20 to 30 per cent. It can be installed in 20 to 30 minutes with no tools other than a file and wrench, and it is so reasonable in price that it will interest a great many Ford owners. For prices and full particulars, address The Perkins Appliance Co., 539 Worthington St., Springfield, Mass.

The "Aeolus" Tire Pump.

This is a powerful compound pump that makes inflation of tires an easy task. It is substantial and long lasting. The pump cylinders are made of seamless brass tubing (not steel) which will not rust, and the joints are positively non-leakable. This is only one of the many desirable styles of tire pumps manufactured by the Bridgeport Brass Company of Bridgeport, Conn., and readers are urged to send to this company for their 1915 catalogue, which describes and illustrates their full line.

A New House Organ.

The Auto Parts Company, Providence, R. I., manufacturer of the Apco line of specialties, is issuing a house organ termed the Ford Dealer. It is published on the 20th of each month and its contents are devoted to the interests of the Ford dealer and garage. It contains much useful information to the trade to whom copies will be mailed free upon request.

The "K. & S." Ratchet Wrench.

This is a very handy ratchet wrench with reverse shift and it makes an important addition to the kit of any motorist or garage owner. This wrench is made of the best material and all parts are interchangeable. For printed matter and particulars, write direct to the manufacturers, Henry M. Kolb, 2311 North 16th Street, Philadelphia, Pa.

Automobile Specialties.

The Nathan Novelty Manufacturing Company, 84 Reade Street, New York City, have just issued a new catalogue in relation to their automobile supplies for Ford cars, as well as motor cycles. It is well illustrated, the price of each article is given, and it will be sent to any dealer or car owner who applies for it, at the cost of a postage stamp.

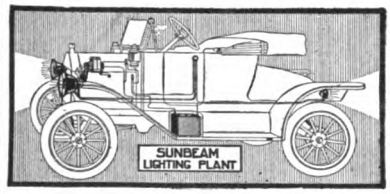
Johnson's Prepared Wax.

This is a preparation for use on the body, hood and fenders of automobiles, whether old or new. The manufacturers state that this wax will preserve the varnish and protect it from the weather. It will cover all small scratches and it minimizes the labor of keeping cars in good condition. Mud spots can be easily and entirely removed from cars that have been polished with this wax. This wax does not gather the dust and it is largely used for polishing floors, linoleum, woodwork, furniture, pianos, etc. The manufacturers want every reader of this magazine to try a can of this wax, and they are therefore making a special offer at this time. If you will cut out the coupon attached to their advertisement in this issue and send it to them, together with ten cents in coin or stamps, they will forward you absolutely free and postpaid, a can of this wax, sufficient for one application on a large car. Fill out the coupon before you forget it and take advantage of this remarkably liberal offer, addressing your request to S. C. Johnson & Son, Racine, Wis. To secure the free can be sure to use the coupon.

A New Auxiliary Seat.

We illustrate a new seat made by the Hill Manufacturing Company of 25-27

Hill's Auxiliary Seat No. 24, Open and Closed.



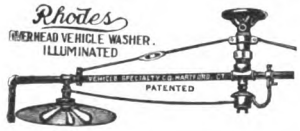
Fuller Street, Buffalo. The seat is round and has a diameter of 13 inches, from the bottom of the seat to the top of the back is 18 inches and the seat folds up flat against the back, thus giving free access to enter the door of the tonneau. The chair revolves and is made with springs in the cushion. This seat is especially adapted to Reo 6 and Overland touring cars, or any car where the tonneau space is somewhat crowded. A large line of other seats is made by the same manufacturers, to whom all inquiries should be addressed.

The Adamson Vulcanizer.

A very handy vulcanizer for motorists which can be easily carried in a touring kit is manufactured by the Adamson Manufacturing Company of East Palestine, Ohio. This vulcanizer is not an experiment, but is in extensive use all over the United States, and it can be found in the kit of half a million or more motorists. This is a simple and practical device and absolutely certain in its operation. It is also so low in price that it is easily within the reach of every motorist. This vulcanizer is made in various styles and sizes and those who are interested should write to the manufacturers for complete information.

The Sunbeam Lighting Outfit.

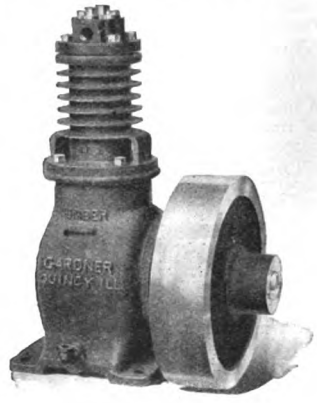
The manufacturers of this outfit guarantee its efficiency in the strongest manner, and the price of the outfit is so low that it is certain to interest many of our readers. It is especially adapted for Ford cars and is equipped where desired with complete brackets for attaching.



Made by Milwaukee Specialty Mfg. Co., Milwaukee, Wis.

The manufacturers have been conducting a test of the generator used on this outfit and after running one of these generators 10 hours per day for 20 days, it was found in perfect condition and at no time did it overheat or fail in any way to work in first-class shape. The price of this lighting outfit is so very low that it is easily within the reach of every Ford car owner. The illustration shows how the outfit appears when attached to the Ford car. For further particulars write to the Milwaukee Specialty Manufacturing Company, who will gladly furnish prices and complete particulars.

Automobile Washers.



The Rhodes Overhead Vehicle Washers are useful for all owners of automobiles and carriages. They are made in two styles, the Excelsior Plain Washer and the Superior Illuminated Washer. The Rhodes Excelsior Plain Washer is designed for use where a direct light on any and all parts of the vehicle are not required. The Rhodes Superior Illuminated Washer is equipped with electric lights, which allows of washing vehicles at night or in a dark place, and will throw a strong light directly on the vehicle to be washed, when you want it and where you want it, and makes daylight conditions where night work is required. This illuminated washer has a special electrical contact box, the result of long experience and which positively insures a perfect electrical contact without any danger of short circuiting,

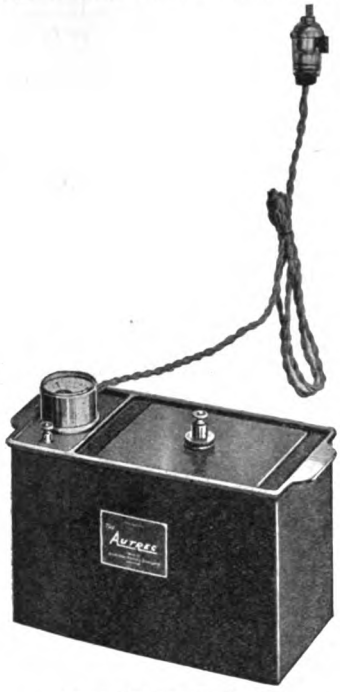
under the most severe conditions, and has been tested and approved by the National Board of Fire Underwriters. By the use of this washer you can reduce your electric light bills, as you do not have to light up the whole four sides of your washstand, and the person doing the washing can do far better work, as the light shines directly on the side of the vehicle, showing up all crevices where dirt would otherwise be concealed. Both models of the Rhodes washer are of simple, strong construction with no complicated parts to get out of order, and all vital parts are made of brass, the rest are wrought or malleable iron, insuring absolutely first-class construction, with an easy, smooth working revolving joint at all times. The washers require only a short piece of hose, which is suspended clear of the ground, and swings around the vehicle being washed, putting the water just where it is needed. The arms extend 4½ feet from the center, thus giving a 9 foot circle, which is sufficient for any ordinary car. They can be made longer or shorter as requested, to meet any special requirements. They are made by The Vehicle Supply Company, 26 State Street, Hartford, Conn.

Gee Gee Garage Pump.

Gardner's "Gee Gee Special" Garage Pump is a thoroughly practical air compressor for use in garages. It is an air-cooled pump with enclosed crank case, which is dirt and dust proof. The lubrication is automatic, through the splash system. Every working part is drenched with oil, which prevents wear and insures long life to the pump. This air compressor under test ran continuously at a speed of 600 revolutions per minute, 150 pounds air pressure, until it had made more than 30,000,000 turns. After this test every working part was

New Garage Pump.

still in perfect condition without a semblance of wear. The machine is well balanced and accurately built and fills the need for a low-priced reliable pump. Write for full particulars to The Gardner Governor Company, Quincy, Ill.



Electrical Starting and Lighting Equipment.

A new and important source of revenue for garage owners has been opened up by the increasing use of the electrical starting and lighting equipment. With the exception of a very few low-priced cars, practically every car now made has this equipment, which includes motor, generator, battery, switches, regulating devices, wiring, lamps, etc. Any dealer or garage owner who doesn't carry this line at present should communicate with the Weston Electrical Instrument Company, 2 Weston Avenue, Newark, N. J. They have a special proposition which should be intensely interesting to every garage owner, and they are making a special offer which will soon be withdrawn. We therefore advise prompt action. This is something worth while and gives the dealer or garage owner control of the cream of high class trade in any given territory.

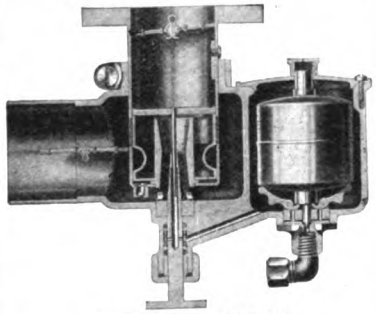
For Battery Recharging.

The device illustrated herewith enables you to charge a 6, 8, 12, 18 or 24 volt storage battery from an alternating current circuit. It is almost as easy to manage as an electric household iron. Screw the attachment plug in any socket where there is alternating current and then run two wires from the Autrec terminals to the storage battery to be charged. The latter may be left on the car. Turn the socket key and the battery will receive a direct current. The Autrec will pass a current of about two amperes or a little lower if the voltage of the battery is high. With this current, you can charge a battery of any ampere-hour capacity if time is not limited. A charging over night will put a discharged battery in serviceable shape, and if the latter is of large ampere-hour capacity, the current may be left on long enough to effect a complete charge, or it may be put on at different times and the same result accomplished. Charging the battery at regular intervals is good practice. Made by the American Battery Company, 1132-1134 Fulton Street, Chicago.

Autrec Battery Recharger.

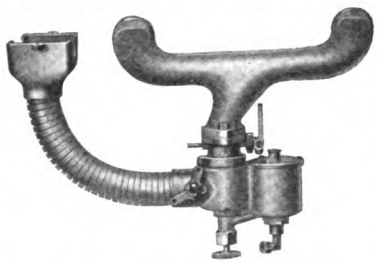
New Spark Plug Line.

The Fulton Company, 726 National Avenue, Milwaukee, Wis., manufacturers of the Aermore Exhaust Horns, are offering a new line of spark plugs under the trade name of Eklips.



In this line is employed imported hand-turned porcelains, insured against breakage by a series of spring washers. Electrodes are of a special heat-resisting alloy, which does not fuse nor flake. A noteworthy construction is the shape of the electrodes, which are so shaped that oil runs to their lowest point to drip off, thus running away from the sparking point. The petticoat of the porcelain is kept well back from the points, leaving a chamber within the steel shell, and serves to clean the plug out at each explosion. Where heat or oil conditions require, a mica core can be furnished, which has strips of mica wrapped around the center core, in addition to the usual washers. The electrodes are extended ¼ inch below the shell, so that the spark occurs in a body of fresh gas near the center of the combustion chamber.

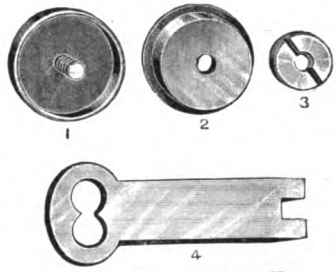
Do You Lock Your Car?



In view of the growing activity and cleverness of automobile thieves not the least of the worries of the auto owner is the chance of finding his car missing when he returns to the place where he left it. From time to time locking devices have been brought out which fulfilled their mission with varying success, but owing to their high cost and the mechanical fitting required, they have not found favor with the average automobile owner. With these conditions in mind the makers of the commercial auto lock have produced a simple device which securely locks the shift lever in the neutral position on all cars having the "H" plate, thus making it impossible for anyone not having the key to move the car. The lock is made of manganese bronze, requires no fitting and to put it within the reach of all who desire to protect themselves from the loss and annoyance of theft, it is being sold at a very modest price, The lock is the production of the Commercial Specialty Company of Cleveland, Ohio, who will be glad to supply you should you be unable to secure one from your dealer.

An Effective Carburetor.

The Frost Manufacturing Company, Kenosha, Wis., make the new Brad-Kent Carburetor which is surely an innovation. Its simplicity, light weight and automatic operation are decidedly novel. It has no cams, springs, or other delicate mechanism to be thrown out of adjustment by vibration. It requires one adjustment only—for gasoline—which is obtained by hand-wheel on underside of the carburetor. The firm manufactures a special equipment for Fords, consisting of carburetor and manifold, hot air tube and stove. It can be installed on any Model "T" Ford automobile in a few minutes by disconnecting and removing manifold and carburetor and replacing with the Brad-Kent carburetor and manifold. No bolts, nuts, screws or washers required, except such as are now on your car.



Brad-Kent Carburetor.

Manifold, hot air tube and stove.

Reliable Puncture Plugs.

There is no preparation necessary to insert and lock the Spitler Tire Puncture Plugs. The operation is clean and simple. It is not always an absolute certainty that a vulcanized repair is going to hold. The Spitler Puncture Plugs clinch and permanently lock the punctures. With both the patch and vulcanized repairs to inner tubes there always remains one or more weak spots in the tube, which are liable to be punctured again just at those spots; then another patch or vulcanizing job is necessary. This is not the case when Spitler Puncture Plugs are used. Another puncture cannot occur just over the spot covered by one of these plugs. They can be used over and over again. They also vulcanize themselves to the inner tube automatically. They are made by B. W. Spitler, 52 Claybourne Street, Dorchester, Mass.

Puncture Plug parts and Key.

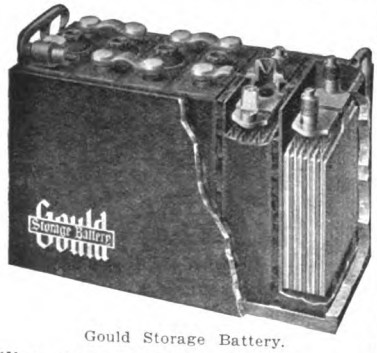
Atwater Kent Unisparker.

For the benefit of automobile owners wishing to replace magneto equipment on their cars for Atwater Kent Ignition, the Atwater Kent Manufacturing Works have produced a special form of mounting. This consists of a base 4½ x 3⅛ inches to fit the standard magneto platform, containing a bevel gear reduction, by which the vertical shaft is run at cam shaft speed. The bevel gears are packed in grease and require no attention. The horizontal shaft projects clear through the housing, so that the drive can be taken from either end, thereby permitting it to run right or left hand to suit the engine.

The Unisparker with this outfit is furnished with or without the automatic advance feature. If automatic advance is furnished, the Unisparker casing is first set in the proper angular position to produce a retarded spark on cranking, and is then clamped fast by the cap screw. Owing to the simplicity of this outfit and its freedom from delicate adjustments it can be installed by the garage man without difficulty.

High-Grade Tire Accessories.

A full line of high-grade tire accessories, including tire covers, reliners, inner and outer shoes, raw stocks, and cementless patches is made by the Chicago Tire Goods Company, 1216 Webster Avenue, Chicago, who will gladly furnish prices and particulars on application.



Digitized by Google

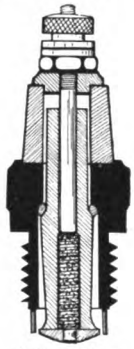
Rapid Growth of a Well-Known Firm.

The recent completion of another addition to the plant of the Atwater-Kent Manufacturing Works in Philadelphia gives further testimony to the extremely rapid rate at which this concern has grown and to the increasing popularity of the ignition system that has made the name famous among automobile owners. The present addition is the twelfth extension which has been made during the last twelve years. It was not considered definitely until the latter part of November, at which time it became apparent that the rapidly growing schedule of deliveries for the spring months would tax the present plant, which, when it was built two years ago, was thought to be of ample size to take care of any normal increase for years to come. The new plant has a capacity of over 700 ignition systems per day.

For Starting, Lighting and Ignition.

The Gould Storage Battery Company, 30 East 42d Street, New York, manufacturers of storage batteries, are now marketing an improved battery for starting, lighting and ignition of gasoline cars. The grids of these batteries are of the same well known Gould type, assuring high conductivity and low internal resistance throughout the life of the plate. The active material in the positive plate is harder than ordinarily used, and wears evenly, the result being more uniform capacity throughout exceptionally long plate life. The maintenance of this uniform or normal capacity throughout the battery life is very desirable, as it permits safe use of a battery having capacity much nearer to actual requirements and one consequently smaller and lighter than where the plates get decidedly weaker with age. A large set-

Gould Storage Battery.



tling chamber at the bottom of each jar permits long service without cleaning. Short circuits between the plates are prevented by wide separation and rugged separators. For business information, address the manufacturers as above.

Parts For Obsolete Cars.

The Puritan Machine Company, 411 Lafayette Boulevard, Detroit, Mich., has been for years making a specialty of the manufacture of parts for cars no longer manufactured. This business of making parts for obsolete cars is quite important, as it accommodates the owners of these cars, who could not otherwise be served except at great expense. Large quantities of the assets of the defunct Krit Motor Car Company and the Krit Motor Sales Company have been purchased by Alfred G. Dunk, president of the Puritan Machine Company, and this company will continue the manufacturing of parts for the Krit, and will also build a limited number of complete cars from the Krit patterns. The Puritan Machine Company makes parts for something like 60 makes of cars which are no longer manufactured.

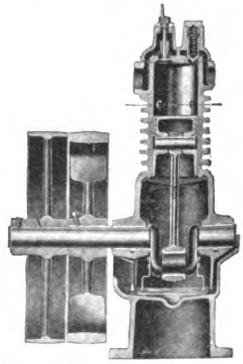
Peco Valve Plug.

The Power and Efficiency Company, of 137-139 East State Street, Trenton, N. J., are placing upon the market in addition to their regular "Peco" two point ignition plug, a single pole plug that is called the "Peco Valve," and bids well to jump into great demand and

A New Plug.

become as popular as their two point ignition plug. The important feature of this plug is the method of seating the porcelain, making an absolute air tight joint with the use of very little pressure or strain upon the porcelain, also eliminating any chances of leakage of the mixture by compression. The seat being reversed from the ordinary plug, placed in the socket from the bottom of the plug, so that the compression acts directly upon the same, and forces the porcelain tighter and tighter by upward pressure against the gasket, similar in action to the compression acting upon a poppet valve. The insulation is composed of two parts, an outer member which surrounds the inner core, and acts as a bridge resting upon the face of the socket. It not only acts as an insulator but also is used as a means of support to hold in place the inner insulation. Ample room is left in the insulation and all other points for free expansion and contraction. The lower end of the electrode is properly threaded to receive the cement and is placed in the porcelain in the same manner that the porcelain is placed in the socket and positively cannot leak. At the end of the insulation and attached to the electrode is a baffle plate made of special non-corroding material from which the spark jumps to the special projecting ground wires, inserted at the bottom of socket or shell. There are four of these special wires in number, so that if any fouling deposit should occur at one point it will automatically change to another point. It can be assembled and dissembled in a minute's time without the aid of any tools. All parts are made from the very best material obtainable for the purpose and highly finished.

Non-Carbene.



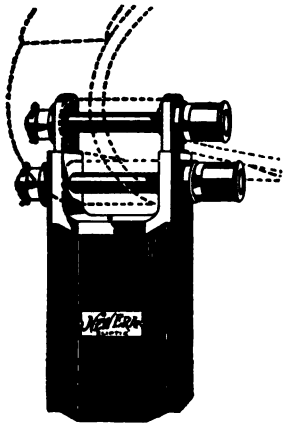
This is described by the manufacturers as a carbon preventer and power stimulator. It is made for use in all internal combustion engines, including automobile, motor truck, motorcycle, motorboat and aeroplane engines. The manufacturers claim that this preparation combined with gasoline will increase your mileage 20 per cent., prevent formation of carbon and improve the running qualities of your car. Non-Carbene is guaranteed to contain neither acid, alcohol, ether or any substance injurious to the carburetor or motor mechanism. Full information will be furnished in regard to this new product if you write to The Noncarbene Company, 1765 Broadway, New York City.

Master Vibrator for Ford Cars.

The modern tendency in motor car equipment is to avoid having the dash littered with all kinds of so-called accessories. For this reason, the master vibrator has not always been acceptable to those who, while convinced as to its possible merits, objected to the apparently makeshift device. Recognizing this natural tendency, the American Coil Company, of Foxboro, Mass., devised a master vibrator which completely removes this objection on the part of many owners and produced a master vibrator identical in material and finish with the Ford coil box and provided an easy method of attaching the vibrator to the coil box in place of the switch. The combination of coil box and master vibrator is perfectly harmonious as it is about the size of an efficient coil switch. The type of cowl dash on this year's Ford practically excludes the installation of an old style vibrator on the dash and, so far, no other vibrator has been produced which can be conveniently attached to the coil box. In this harmonious combination of vibrator and coil, all extra wiring is eliminated. The only thing necessary to do is to detach the switch, put the vibrator in its place and attach the switch wires to the vibrator.

A Fine Garage Pump.

Illustrated herewith is the Curtis Common Sense Garage Pump, manufactured by the Curtis Pneumatic Ma-



A Powerful Garage Air Pump.

chinery Company, 1530 Kienlen Avenue, St. Louis, Mo. It will pump from 2 to 24 cubic feet of air per minute, costs very little to operate, and it was designed after 20 years' experience in air appliances and machinery. It will probably never get out of order much less wear out, and is always ready for business on an instant's notice. Address the manufacturers for further information.

A Shock Absorber of Merit.

The New Era Eliptic Shock Absorber, for light, medium and heavyweight cars, having simplified construction and handsome design that will appeal to the vast number of owners needing more comfort and desiring to save the car from excessive abuse. Any user of absorbers will readily state they are almost a necessity, and it is a fact that they will more than save their cost in a season on tires alone, and frequently

on springs. The efficiency of the New Era gives great resiliency and absorption of constant vibration of all small depressions and by its double spiral vanadium springs of scientific apportionment and adjustment for the weight of car intended, produced the ideal shock absorber at a price all can easily afford to buy. This shock absorber is low in price and practically indestructible. It is made by the New Era Spring and Specialty Company, Detroit, Mich.

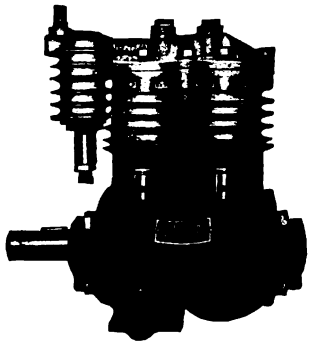
Motor Touring and Camping Specialties.

Many motorists who are contemplating an extended tour do not fully realize what is necessary in the way of equipment, and the Kansas City Automobile Supply Company, Kansas City, Mo., is making a specialty of giving this information. They will be only too glad, without charge, to help all interested automobile owners, and they will bring out a special number of what they call the Service News, to be issued April 1st, 1915. Any readers who may be interested in this publication should cut out the coupon appearing in the advertisement of this company in the present issue and send it on to them with your name and address. If you will do this the Service News will be mailed absolutely free of charge.

Universal Treads and Repair Boots.

The Indiana Specialty Manufacturing Company, Angola, Ind., has purchased the plant and property of the Universal Protector Company, and they have for sale a moderate stock of strictly first quality, new treads and repair boots, which were manufactured by the Universal Company before the change in ownership. They quote very reasonable prices on these repair specialties and any who are interested should write direct to the Indiana Specialty Manufacturing Company for full particulars, or consult the advertisement in this magazine for prices.

Northeast System of Starting and Lighting.



A system of electric starting and lighting for the Ford car, which is highly recommended, has been brought out by the Northeast Electric Company, of Rochester, N. Y. This apparatus cranks the motor, gives a brilliant light at all times and charges the storage battery. The manufacturer states that any garage man can install this in a few hours and no change of the Ford car is necessary. Readers who are interested should write for prices and complete description direct to the manufacturer. In all correspondence if you are interested in this outfit, be sure to write for Bulletin 30-A.

Burd High Compression Piston Rings.

The manufacturers state that these piston rings are absolutely reliable and 98 per cent. efficient. They also say that they will positively hold the compression so that the motor will deliver full power. There is nothing fancy about Burd rings—they are just plain, honest, old-fashioned piston rings, accurately made—the kind all engineers endorse, and the opening in the piston ring is guarded so that it cannot leak. For prices and full particulars readers are requested to write direct to the Burd High Compression Ring Company, Rockford, Ill.

"Purair" Tire Pump.

This is a good motor-driven tire pump. It is manufactured either with one or two cylinders and we illustrate the two-cylinder pump herewith. This pump may be easily installed by anyone, as no machine work or special tools are required. In most cases it is only necessary to re-

Effective and Compact.

move two cap screws and put them back again with bracket in place, and clamp split gear to its shaft. Full directions are sent out with each pump. For full particulars write direct to The Hert Manufacturing Company, Indianapolis, Ind.

An Interesting Catalogue.

The Standard Auto Supply Company, 97 Chambers Street, New York City, have brought out their new catalogue for 1915, which includes a great variety of automobile supplies. This company claims to save you considerable as compared with the ordinary local dealer. If you will write for this catalogue it will be sent free and post paid on application.

The Pneu-Meter.

The well known automatic tire pressure gauge which was placed on the market by the Hill Pump Valve Company, of Chicago, in 1913, has recently been improved in a very striking way, so as to make it a simple piece of mechanism. This device controls tire pressure from 40 to 120 pounds, and is graded in 5 pound units. Its simplicity and its accuracy are its most striking features.

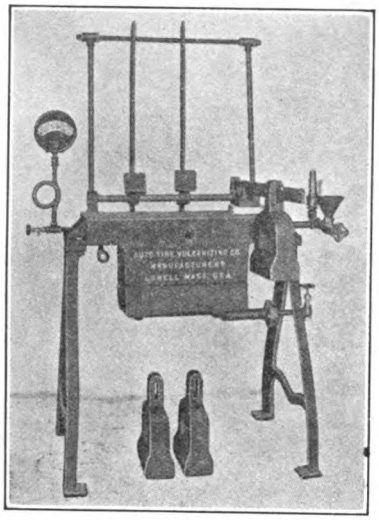
Novel Tire Pressure Gauge.

To operate this device, one merely sets it at the correct pressure desired, and when the tire is inflated at this point, the Pneu-Meter becomes a safety blow-off valve, and all excess pressure escapes through an exhaust port, with a shrill whistling noise which can be heard fully a block away. The manufacturers state that this automatic device allows the motorist to put away his tools or do any other work which he desires, while the pump is inflating his tires without any danger whatever of over-inflation. The Pneu-Meter is installed on the hose line of all Utility and Utility Jr. Pumps made by this firm, as well as is furnished separately for use in connection with other power pumps or garage air tanks.

Auto Tires at Wholesale.

The Kenmore Manufacturing Company, 320 Bromide Building, Chicago, Ill., is offering automobile tires at wholesale prices to introduce them quickly in towns where they have no dealers. These tires are of all sizes and types, and readers are urged to write to this firm direct for catalogue and the special introductory offer.

A Special Ford Turntable.



A special turntable for Ford cars has been placed upon the market by the Pitless Auto Turntable Co., 2400 Broadway, Kansas City, Mo. This turntable is made with all steel runways ball bearings throughout, and it is stated that you can turn your Ford car with your little finger, and that this turntable will last a lifetime. This is adapted not only for Ford cars, but any light car up to 108 inch wheel base, and it is sold at a very low price. Correspondence especially from Ford owners is invited.

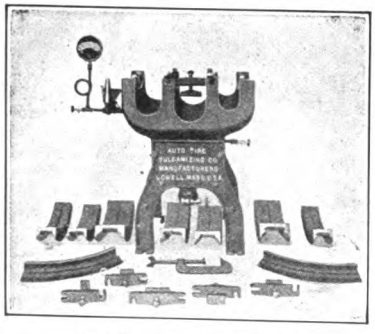
High Class Vulcanizers.



Illustrated herewith are two vulcanizers of the line made by the Auto Tire Vulcanizing Company, of Lowell, Mass. No. 8 vulcanizers will cure perfectly any tire made, either foreign or American make, from 3 in. to 5½ in., including all the various makes of clincher, quick detachable and straight side tires. The vulcanizer is equipped with steam gauge, water gauge, safety valve, filler and filler

No. 2 Tube Vulcanizer.

valve and gas burner with burner valve, so that steam can be generated in the vulcanizer. It is steam jacketed and like other vulcanizers of their make is cast in one piece having no packed or bolted joints, thus avoiding the possibility of leaks. The vulcanizer is very compact, it occupies a space only 27 in. long and 21 in. wide.

The No. 2 tube vulcanizer is made of semi-steel. It is fitted with three weights and levers. The top of the vulcanizer is finely machine finished and polished. It is 20 in. long, 7½ in. wide

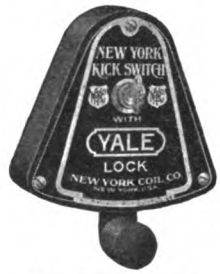
No. 8 Sectional Vulcanizer.

and 7 in. deep at water chamber. It is complete with steam gauge, water gauge, safety valve, filler and filler valve and gas burner to generate its own steam. All the vulcanizers of this well-known firm are guaranteed and they are not offering vulcanizers in the experimental stage, but vulcanizers which have been thoroughly tested and approved, by some of the best tire manufacturers and experienced tire repair men.

1915 Pilot Models.

Among the new models for 1915 which are attracting a lot of attention among buyers of good automobiles are the standard Light Six and the Pilot 75 made by the Pilot Car Sales Company, Richmond, Ind. For years this firm has been making the highest grade cars and selling them at very reasonable prices and a study of their new models shows a great many things which should interest an automobile buyer. Pilots have always been noted for their wonderful power and strength, and the new models are striking examples of sturdiness in construction. Pilot 75 is becoming recognized as a wonderful hill climbing car. Among recent performances in hill climbing on high gear are climbing Carr Hill, Tacoma, Wash., a long 20 per cent. grade, difficult of approach over five hills of lower grade; climbing from Colorado Springs to Cripple Creek, 44½ miles, in one hour and thirty-eight minutes and rising 4,500 feet in altitude; climbing Ute Pass, Colorado Springs; taking five passengers from Nashua, N. H., through the White Mountains and return without changing gears; taking the long side of Corey Hill in Boston with a full load of seven passengers at thirty-five miles per hour; Angel Street in Providence, R. I., at thirty miles per hour, and all the important hills known to tourists in Pennsylvania. The Pilot Car Sales Company for a year have issued a challenge to any and all stock pleasure cars, regardless of size, weight, price or number of cylinders to a hill climbing contest with Pilot 75. The Pilot 55, the Light Six, is equipped with a 3⅞ x 5¼ Teetor motor, giving 63 horsepower and as the car weighs but 3,175 pounds, which is equivalent to about one horse-power to each fifty pounds of weight, the Light Six should be in the Light Six class as great a hill climber as the Pilot 75 is in the larger car class.

Waterhouse Welding Outfits.



The automobile dealer, repairman, or garage owner who has not yet installed an oxyacetylene welding outfit is losing an opportunity to make considerable extra money to say nothing of the great accommodation to customers. A good outfit is made at a very reasonable price by the Waterhouse Welding Company, 16 Pelham Street, Boston, Mass. This outfit includes everything that is needed for doing this work and it includes complete instructions dealing with the treatment of repairs of all kinds of metal. This outfit is put on the market at a remarkably low price and yet all the apparatus furnished is absolutely guaranteed as to quality.

Apex Electric Air Compressor.

This is an excellent two-cylinder air compressor suitable for use in private and public garages. It pumps air direct into the tire and no storage tank is necessary. To operate it it is only necessary to attach to any electric lamp socket. This device is manufactured by the Apex Electric Manufacturing Company, 1410-12 West 59th Street, Chicago, Ill. This company also manufactures the celebrated "Yankee" Folding Tire Pump and the Apex Multiple-Cartridge Electric Soldering Irons. Write for illustrated printed matter and full information.

N. Y. Coil Co.'s Latest.

The New York Coil Company, of 338 Pearl Street, New York City, N. Y., manufacturers of the well known Uni-Coil ignition system, model "T" master vibrators, Ford lubricating devices, shock absorbers, etc., have just placed upon the market their New York Kick Switch with Yale lock. This switch is designed in such a manner that the three holes for attaching to the Ford metal coil box register so that all that is necessary is to remove the present switch and by means of the three bolts, secure the switch in position and con-

New Lock Switch.

nect the three wires to the connections marked 1, 2, 3, which may be accomplished in a few minutes without the splicing of wires or the slightest difficulty. This switch is an entirely new departure from anything heretofore offered in the lock switch line, to all outward appearances it represents the regular kick switch, but has incorporated in its construction a genuine Yale lock. When the key of the lock is turned the ignition circuit is locked in the "off" or "on" position, effectively preventing the loss of your car by theft, or its use by unauthorized persons. It will therefore be seen that the convenience of the kick switch is secured as well as the protection afforded by the locking feature. The switch may also be used on wood coil boxes or dash without change..

The Conover Cowl-Windshield.

This is a special windshield for Ford cars and thousands of Fords are already

equipped with it in all parts of the country. This shield has ventilating top and bottom which is automatic in action and it also has provision for rain vision and a clear view of the road. It may be used on Model T Ford cars of 1912, 1913, 1914 and 1915, and it bolts on without fitting. In appearance it is exactly like the shields used on higher price cars. Dealers are finding this line easy to sell and very profitable. For full particulars write to the Page Woven Wire Fence Company (Windshield Dept.), Adrian, Mich.

Transmission Band Assembly for Ford Cars.

We illustrate a new transmission band assembly for Ford cars which is called the Ideal Transmission Band Assembly. It consists of a highly tempered steel band with two detachable shoulders, which being easily removed enable any mechanic to extract the band and replace it in one-sixth of the time that it can be done under ordinary circumstances. This device is lined with a good quality of asbestos band lining, and this advantage will undoubtedly appeal to many of our readers. It is manufactured by the Metal Stamping Company, Long Island City, N. Y., to whom all inquiries in regard to price, etc., should be addressed.

Marvel-Mist.

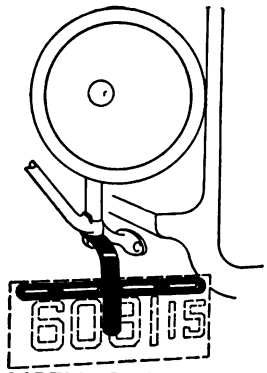
This is a preparation for cleaning and polishing the varnish surfaces of automobiles, also the metallic and leather portions of the car by spraying a light vapor of Marvel-Mist over any part of the car, including the body, hood, fenders, leather, upholstery, top windshields, or lamp lenses, a high polish is obtained, the finish is preserved, and the car is perfectly and completely cleansed. Marvel-Mist is applied through a sprayer similar in effect to the ordinary medical atomizer and should never be used in ordinary liquid form. Marvel-Mist is guaranteed to be absolutely free from acids, alkali or grease. It never hardens, does not collect dust or dirt and will not evaporate or dry out when lying idle. This preparation is sold in a one pint can with combination sprayer and cloth or one quart with the same equipment. The price is reasonable. Address your orders and inquiries to the Marvel-Mist Manufacturing Company, 48-54 Greenpoint Avenue, Brooklyn, N. Y.

The Marvel-Mist Trade Mark.

New Witte Engine Catalogue.

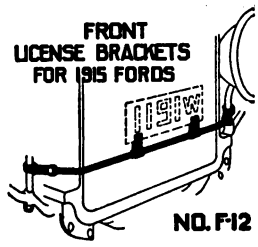
The new catalogue, No. 46, of the Witte Engine Works, 2494 Oakland Avenue, Kansas City, Mo., is just out. It contains much of interest to every intending engine buyer. The matter on two pages alone, pages 4 and 5, "Lower Cost of Engine Power," shows the big stride made in the last two or three years in the reduction of cost of dependable gasoline and kerosene engine power. Price making and operation cost are here figured out with striking plainness. Whether any of our readers should ever buy a Witte engine or not, the Witte catalogue is worth careful reading, for it shows the interest of the engine user in his possession and use of an engine in a way that everyone ought to see, whichever engine he may later buy. A 6 H. P. Witte at $97.75 sets a new low mark in prices, as indeed do the prices on all the other of the seven Witte sizes and the 36 styles in which the various sizes are furnished. Any of our readers can secure one of the new catalogues by writing for it, to the address above given.

"Air-In-Al."



A new preparation called "Air-In-Al" has been put on the market and the manufacturers state that it will seal punctures in automobile tires instantly. It is simple to use and is non-injurious to rubber, paint, varnish or clothing, and can be removed from same with cold water. This is an extremely handy thing to have in your tool-kit while touring, and the price is so low that it is within the reach of all. Some choice territory on this article is open to live dealers. Readers are urged to send for circular and full particulars immediately, addressing inquiries to the Woodbridge Chemical Company, Inc., U. S. Rubber Company Building, New York.

Magneto Parts for the Trade.



The Magneto Parts Company, Inc., 1790 Broadway, New York, are furnishing interchangeable parts for all standard makes of magnetos, including Bosch, Eisemann, Splitdorf, Remy and Mea for several types of magnetos. These parts are absolutely interchangeable and they are guaranteed to give satisfactory service. This will undoubtedly be interesting to many repair shops, and repairmen are urged to write to this company for complete catalogue containing parts listed with their respective prices. Get full particulars on the attractive agency proposition offered by this company.

Attractive Specialties.

Illustrated herewith will be found a new 1915 model of license bracket for Ford cars. It will be noted that these cars require special license brackets, both front and rear. The illustrations will give an idea of their advantages. They are easily attached, neat, substantial and well finished in black enamel.

Another valuable accessory for the Ford car is the new steering wheel shown herewith. As will be seen it is larger than usual, giving greater leverage and making steering very much easier. With it, there is no danger of the Ford car getting away from its driver on any road or locality.

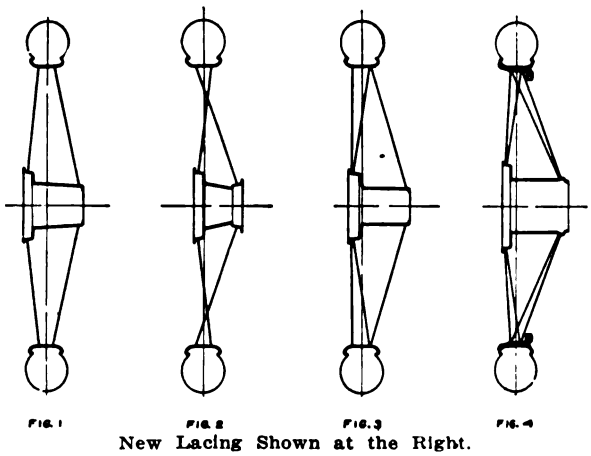
The Garage Equipment Manufacturing Company of Milwaukee, Wis., makes a wide range of accessories for Ford cars, and they are all of good workmanship, practical, and low in price.

New Firestone Tire.

A new tire designed especially for use on electric pleasure cars has been developed by the Firestone Tire & Rubber Company, Akron, Ohio, and was recently placed on the market. The new pneumatic is built up with unusually heavy gum cushions between the layers of fabric to provide a high degree of resiliency; the construction is worked out with a view to obtaining the greatest possible economy of power, and the makers state that the result has been very satisfactory. But one type of tread is used—the Firestone dual tread, in which there is a central depression between two raised sections.

Digitized by Google

Improved Wire Wheel.



The General Rim Company, Cleveland, Ohio, has perfected and now is placing on the market a new type of demountable, detachable rim designated to overcome the effect of excessive unbalanced weight. Combined with this is a simple and effective arrangement for attaching the rim to the wheel band which eliminates all nuts, bolts, wedges or other loose parts. At the same time the company is marketing a quadruple-laced wire wheel designed to carry this rim equipment. Although it has not always been customary to take into account the weight of the spreader, valve stem, nut, dust cap, etc., with which every pneumatic tube is fitted, General Manager F. Hughes Moyer of the General Rim Company, points out that, "Any automobile wheel, not in perfect balance, has an unbalanced action, when rotating, which resolves itself into a pound on the tire in varying amounts, depending upon the speed and the amount it is out of balance."

In the new G-R-C wire wheel the spokes are in four planes, so designed that every spoke in the wheel can and does take its share of side strain, producing a wire wheel in which all strains are balanced. Rim and wheel construction is covered by patents or patents pending.

Fig. 1 shows the original form of wire spoke lacing as applied to automobiles. Fig. 2 shows the cross bracing which followed later. Fig. 3 shows the partially braced construction. Fig. 4 shows General Rim Company lacing.

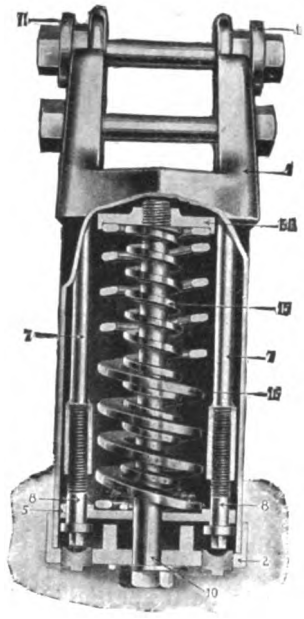
All four types will carry the same vertical driving and braking load. The wheel shown in Fig. 4 is the only one in which the full value of each spoke can be utilized to resist side strain, and in which side strain is balanced.

The improvements mentioned seem to be unquestionable and useful. A mechanically correct rim is important and with this new form of lacing wire wheels will soon "come into their own."

New Lacing Shown at the Right.

New Rim Attachment.

A Robe Lock.



A device which removes the possibility of losing robes by theft from the car has been placed upon the market by the Robe Lock Company, Inc., Oakland, Calif. This will appeal to every motorist and many of our readers will undoubtedly write direct to the manufacturers for prices and full particulars.

New Magnet Charger.

The Kokomo Electric Company of Kokomo, Ind., is manufacturing the Kingston magnet charger for Ford cars. With this charger, which works on a 12-volt storage battery, the magnets on a Ford magneto may be charged to full saturation without removing them from the car and the magnets on all other types of magnetos may be fully charged by removing them from the magneto.

A New Shock Absorber.

We illustrate the Flaum Shock Absorber, a new device which is meeting with favor. This absorber is simple and effective and instantaneously adjustable to all load and road conditions. There

are no wearing parts or friction surfaces, consequently no oiling parts or packing in grease is necessary. For further particulars address Flaum Shock Absorber Company, 173-175 Hudson Street, New York City.

A Line of Garage Equipment.

An unusually attractive line of garage equipment will be advertised in the next issue of the Automobile Dealer and Repairer by the United Engine & Manufacturing Company, Hanover, Pa. Watch for their important announcement.

Chaney Automobile Headlight Dimmer.

This is a device to prevent the danger and inconvenience often caused, especially in city streets, by the blinding glare of automobile headlights. This invention enables the driver to graduate the intensity of the light. It can be changed from high to low as you would turn down an oil lamp and it gives complete control of the headlights from the seat. Dealers as well as car owners are urged to write for full particulars, and address inquiries to the L. F. Chaney Company, Springfield, Ohio.

Housel's Improved Ford Starter.

Housel Sales Company, Inc., of Buffalo, N. Y., is making a special offer to our readers, and they propose to sell 500 starters at a very low price on the basis of cash with order, and for further particulars readers are referred to the advertisement of this company. They also manufacture what is called the "Two Minute" Tire Tool for clincher tires, which is also sold at a very low price. Asch & Co., 1777 Broadway, New York, are acting as Eastern distributors for the goods manufactured by the Housel Sales Company, and inquiries may be addressed either to them or to the main office at Buffalo.

Pumpelly Battery Company.

This well-known company manufactures a large line of storage batteries and last July they moved into a new factory at 34 East Georgia Street, Indianapolis, Ind. In addition to supplying some of the leading factories with storage batteries, such as the Maxwell, Crow, Sphinx, Premier, Hercules, and others, this company is also putting out batteries for every car and starter and they make them to fit every size and shape of standard battery box. The battery was first brought out by Mr. James K. Pumpelly, and it is claimed that he is the founder of the battery business in the United States, having built the first practical storage battery in 1883 for use with Edison phonographs. Mr. Pumpelly is now 85 years old, but he is still active in the business. The officers of the Pumpelly Battery Company are: Harry Murphy, president; James K. Pumpelly, vice-president, and S. W. Elston, secretary and treasurer.

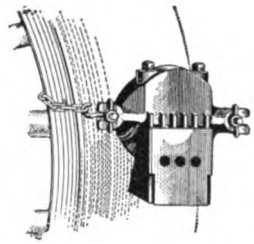
"WIZARD" AND "G WIZ"

STEAM VULCANIZERS

WILL CUT YOUR TIRE EXPENSE IN HALF

HOW TO GET MORE MILES OUT OF YOUR TIRES: You lose thousands of tire miles by not keeping them properly inflated; by applying brakes too quickly, by rubbing against curb stones, by letting car set on oily floors, etc. However, the greatest abuse is to **neglect those small cuts in casings.** Layers of fabric supply strength to the tire, and the rubber covering is to protect them. Small cuts expose the fabric to water and sand, forming sand blisters and rotting the fabric. A blowout at the weakened spot is the sure result. Keep those cuts vulcanized and your tire will last until the rubber tread is worn off all the way around, giving you double the usual mileage.

WHICH IS THE BEST VULCANIZER FOR YOU? The fact that we are the oldest and largest manufacturer of portable steam vulcanizers in the world should mean a lot to you in deciding. Our vulcanizers have been adopted by the U. S. and many foreign governments, and are recommended by the large tire factories. We use **steam heat** in all our machines. **Steam** will not burn or overcure the tire. **Steam** is used by **all** tire makers and large repair shops **exclusively.** Our long experience and large factory facilities guarantee you a better vulcanizer for less money than you can get elsewhere. If you do not find it so, send it back and get your money.

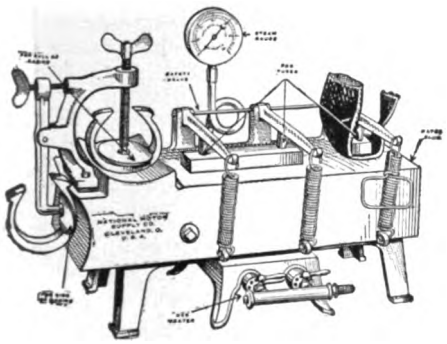


WIZARD Automatic Steam Vulcanizer

For both tubes and casings of any size. Burns gasoline with no smoke and no flame exposed. Requires no watching, as heat is automatically controlled. Water put in at factory and never needs refilling. Steam is the only safe method of vulcanizing. Vulcanizing surface 3″x6″, curved for casings and clamps against plate for tubes. Highly polished and nickel plated all over. Insulated handle. Weight six pounds. It has saved thousands of dollars for our customers. No experience required to use it.

PRICE, With Instructions and All Supplies by Mail, Prepaid, $3.50

Order to-day and save those tires.



G-WIZ Automatic Steam Vulcanizer

For both tubes and casings 3½″ or smaller. Works like Wizard in every way, the only difference being that it is made for small tires. Guaranteed to do perfect work. Thousands of satisfied users. Saves its cost in repairing one tire, and will last forever. Weight 3 lbs.

PRICE, With Instructions and All Supplies by Mail, Prepaid, $1.80

10 DAYS' FREE TRIAL! After you have tried any of our vulcanizers ten days, if not entirely satisfied, return, get your money.

GARAGE AND REPAIR MEN, LOOK!

Thousands of garagemen all over the world are making big profits with our

National Garage Steam Vulcanizer

Vulcanizes three tubes and two casings at a time. Heated by either gas or gasoline. We have made this machine without any change for six years, which shows how satisfactory it is. You might as well have the big profits for vulcanizing in your vicinity. The National is the easiest and cheapest machine to operate on the market.

LIST PRICE, $60.00

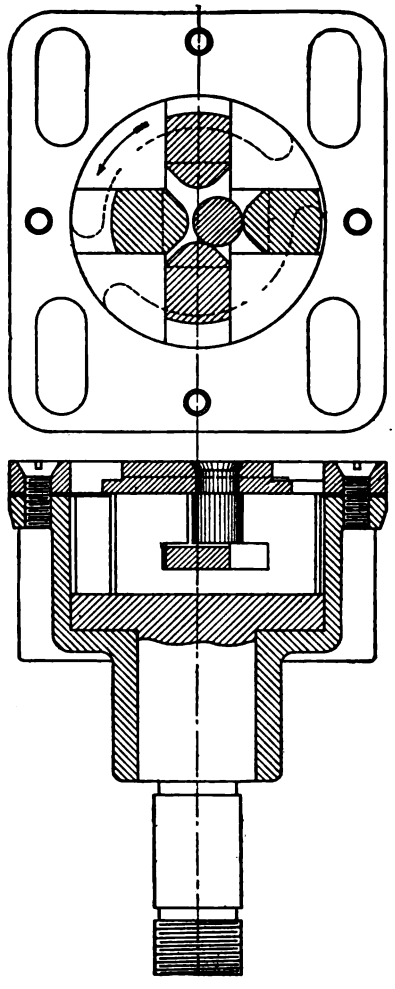
Bethlehem Spark Plug.

The Silvex Company announce the consummation of an arrangement with the New York Sporting Goods Company, 17 Warren Street, New York, which certainly seems to be about the limit in manufacturers' co-operation with a jobber. The Silvex Company are advertising their plugs in the New York City

Note the Name.

subway and are now in the second year of a three-year contract. They have arranged to run the New York Sporting Goods Company's name and address on all their cards as distributors of the Bethlehem Motorcycle Plug, and, in addition thereto, will give the New York Sporting Goods Company representation on their Indian Motorcycle and Smith Motor Wheel line, of which they are the exclusive distributors throughout a big Eastern territory.

Sales Manager Fischer, in comment-



Spark Plug Case.

ing on this item, said: "The Silvex Company has been the pioneer in offering co-operation of the most intensive kind to the jobber, and, while this particular case is an extreme, we have offered similar forms of co-operation all over the Union to jobbers and dealers who, by live sales work and exhibition of "pep," show their friendly co-operation and desire to get out and get the business. Every effort of the Silvex Company has been to establish the closest relations with its accounts, and such a policy we are certain will be appreciated to the full in the long run.

The Pederson Oil Pump.

A new type of oil pump has been brought out by the Pederson Lubricator Company, 644 First Avenue, New York City. It is a rotating pump, the rotating member containing two double acting plungers. The whole is enclosed in a stationary casing, in the cover of which are slots which act as inlet and outlet ports for the slots which are the cylinders of the pump. The illustration will give a good idea as to the practical

Pedersen Rotating Plunger Oil Pump.

working of this pump. As shown in the cut, the right-hand end of one plunger is at the end of the discharge stroke, and the left-hand end at the end of the intake stroke, while the upper end of the other plunger is at about the middle of the inlet stroke and the lower end on the discharge stroke. The positions of the discharge and inlet ports in the head are indicated by dotted lines in the plan view. The pump is a self-contained unit like a gear pump and it gives a continuous discharge, but it has the ample wearing surfaces of the plunger type. The size shown gives a discharge of one gallon per 600 revolutions.

Utility Varnish Renovator.

This is a compound which the manufacturers state will keep the varnish on an automobile looking good as new. It is non-acid, non-alkali, and will not injure the finest surface. Readers who are interested should ask their jobber, or send direct for trial size to the Poughkeepsie Utilities Corporation, Dept. A, Poughkeepsie, N. Y.

"Arclite" Glass Spark Plug.

This is a spark plug embodying an entirely new idea in plug construction. It has a brass base, the threads of which will not damage the cast iron threads of the cylinder, and also will not "freeze" by rusting and releases easily on un-

screwing. The glass is pressed and locked solid within the shell and is of the highest insulating material known. The sparking points are heat-resisting nickel, and will not pit, corrode or burn. This plug shows by flash light color rays the true mixture of gas on explosion in the cylinder; it gives a blue light for the best mixture and yellow for poor mixture. With this plug the engine can be tuned up and the carburetor set quickly, and even the carbon deposit in a cylinder is shown by the color of the light. The manufacturers also state that this spark plug is not affected by heat, cold, or water spray. The "Arclite" is made by Long Brothers, Kokomo, Indiana, to whom all inquiries should be addressed.

New Radiator for Fords.

We illustrate a V-Type radiator for Ford cars, which is manufactured by the Superior Lamp Manufacturing Company,

V Type for Ford Cars.

136 W. 52nd St., N. Y. This is made in brass or German silver finish as desired, and it adds very much to the appearance of a Ford car. The same firm also repairs all makes of radiators and builds special radiators to order. Correspondence is invited.

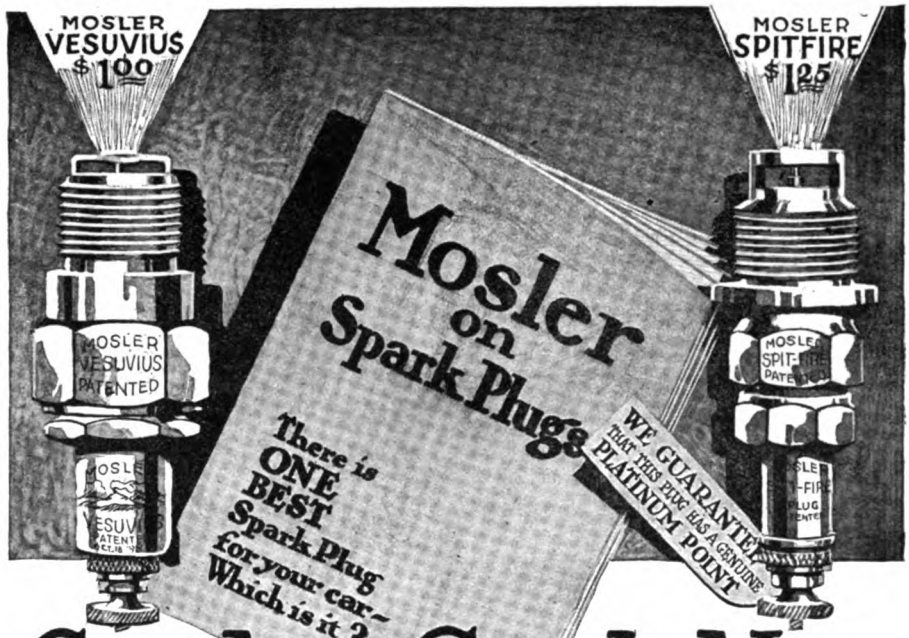
Mosler's Big Advertising Campaign is Under Way

THREE MILLION, SIX HUNDRED THOUSAND consumers are reading the advertisement reproduced below. They will read others like it next month and each month thereafter. This advertising is being done for *you*—it must benefit you before it can show us any return for our heavy outlay.

Are you ready to cash in on the business we are building for you? Or is somebody else going to collect the profits? You can have them for the taking if you stock up with

SPIT-FIRE and VESUVIUS



Get them from your jobber NOW! You can't lose on them—they have always sold on their merits without advertising—they will sell better than ever now. Don't hesitate—every day you wait costs you money.

We are trying our hardest to put money into your pocket. All you need is to have the two plugs—SPIT-FIRE and VESUVIUS on hand. If you'll attend to that we'll do the rest.

"Mosler on Spark-Plugs"

—the new Mosler guide which tells the right kind, size and type of plug for any engine, is now ready for distribution. Write us NOW for a FREE supply—your customers will be pleased if you distribute them. How many shall we send you?

A. R. Mosler & Co.
Mt. Vernon, N. Y.

Get this Guide Now

"MOSLER on Spark Plugs" tells at a glance just which kind, type and size of plug *your* engine needs. Until you equip with that *one best* plug you waste gas and current, lose speed and power, invite ignition trouble. Get this **free** guide now—at your dealer's or by mail—equip as it directs and see what real plug-service means. You can safely take advice from A. R. Mosler, the pioneer of the spark-plug industry, the inventor of the famous **Spit-Fire** and **Vesuvius** plugs.

Mosler's SPIT-FIRE $1.25 Literally *spits-fire* throughout the mixture, insuring, swift, uniform, complete combustion and getting all the power out of the gas. Spark-length adjustable at will; proof against leakage, soot, water, oil and heat. Standard equipment on such cars as the Pierce-Arrow; ideal for Packard, Peerless, etc. Insist on the RED-TAG which guarantees you the ever-lasting IRIDIUM PLATINUM points.

Mosler's VESUVIUS $1.00 Stone-insulated, open-end plug defies heat, oil, water and soot; absolutely gas-tight; continuous knife-edge electrode with innumerable sparking-points. Easy to clean, efficient, ever-lasting. Standard equipment on Pierce-Arrow, etc.

Ask Your Dealer

If he can't supply, we mail postpaid on receipt of price. (Specify car; mention dealer.) Write for "Mosler on Spark-Plugs"—free.

Letting Well Enough Alone.

The Massachusetts Legislature has just turned down two bills which would have limited automobile speed to 30 miles an hour outside thickly settled districts. The present law practically allows the driver to use his own discretion in such districts.

Awakened Garage Owners.

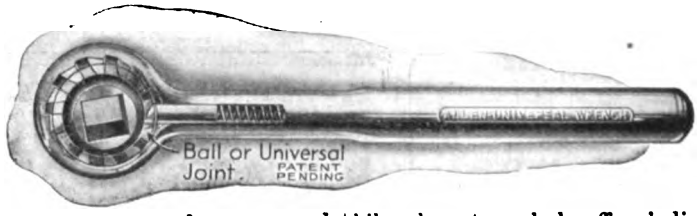
Under the title of the Garage Owners' Protective Association of New Jersey the garage owners of Newark and surrounding territory have organized for their mutual protection and to advance the general business to a higher standard. The new association is to be state-wide in its activities and will include in its membership garage owners throughout New Jersey.

Automobile Turntables.

The Canton Foundry and Machine Company of Canton, Ohio, have published an interesting booklet in relation to their turntables. It is well illustrated, attractively printed, gives useful information and is extremely reasonable. Those who have an idea of purchasing a turntable, or want to learn all about them, ought to write and get a copy of this booklet.

An Efficient Piston Ring.

Readers are frequently inquiring as to the efficiency of various kinds of piston rings and no doubt defective piston rings give a good deal of trouble. There is nothing that interferes with the good service of an automobile more than poor compression, and of course good com-



pression cannot be expected with poor piston rings. It is claimed for the Peerless piston ring that it gives the minimum of leak with very little friction indeed. The manufacturers are so confident it will give satisfaction that they will send one to any engineering organization for the purpose of making a test of it in comparison with any other make of piston rings. They guarantee it to produce more power and to save more lubricating oil and to make less wear of the engine cylinders than the ordinary piston ring or they will refund the money for it. It is made by the Peerless Piston Ring Company, 91-107 Lafayette Street, Newark, N. J.

For Carbon Removing and Welding.

An outfit for welding and carbon removing, at a low price, is being put on the market by the Dyer Apparatus Company, 155 Brookline Street, Cambridge, Mass. It is claimed the outfit has just as wide a range of work as the highest priced, and it will do about everything that is likely to come into a garage or repair shop. As is well known, carbon removing by the oxyacetylene process is considered one of the best methods for thoroughly doing this work. For full particulars write for catalogue and prices, addressing the firm as stated above.

New Socket Wrench.

The Allen Wrench & Tool Company of Providence, R. I., have recently brought out a new line of socket wrench sets. This wrench has what may be termed universal action. It is made from a drop forging and as it has a universal joint it can be used at any angle. It will immediately appeal to mechanics as

being something new and very much needed in work shops.

New Ford Models.

New Ford models show some changes, the changes being principally in the body and appearance, the model T chassis adhering to standard Ford practice except that the flywheel magneto has been somewhat enlarged to take care of the lighting of the electric headlamps, which now are standard equipment. Control of the lamps is through a dash switch. The side and tail lamps are oil-burning but of new form. They are more compact and better conform to the body lines. The most noticeable change is the incorporation of a pressed steel dash in place of a flat wood type. The switches and other apparatus are placed under a cowl on the dash. Other improvement are in the windshield, which is a stronger and more compact type to fit the cowl, and louvres in the hood to give better ventilation to the engine. Another noticeable change is in the rear mudguards, which now conform to the curve of the wheels instead of running straight back horizontally from the point of greatest height. The guards are heavier than the former ones, and their form admits of better bracing against rattle.

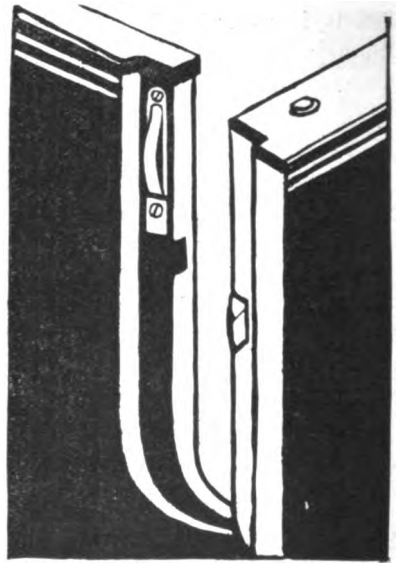
A New Starter.

A new automobile starter which differs from anything yet put on the market in some respects, is said to start the car every time and is fully guaranteed. It is low in price, durable and is made by the Sandbo Starter Company, 34 Sandbo Building, Rock Island, Ill.

Car Polish.

A well recommended car polish is that made by the U-Sav-Your Manufacturing Company, Warren, Mass. The statement that it is well recommended is made advisedly as the firm has no end of letters expressing the satisfaction of thousands who have used it. One man states it has made a very decided saving in the time of polishing his car and has greatly improved its appearance. He says that with its use the varnish seems as perfect as when it first came from the shop. This firm has a proposition by which thousands who wish to try it can do so for a little or nothing by addressing the manufacturers as above.

A Better Law.



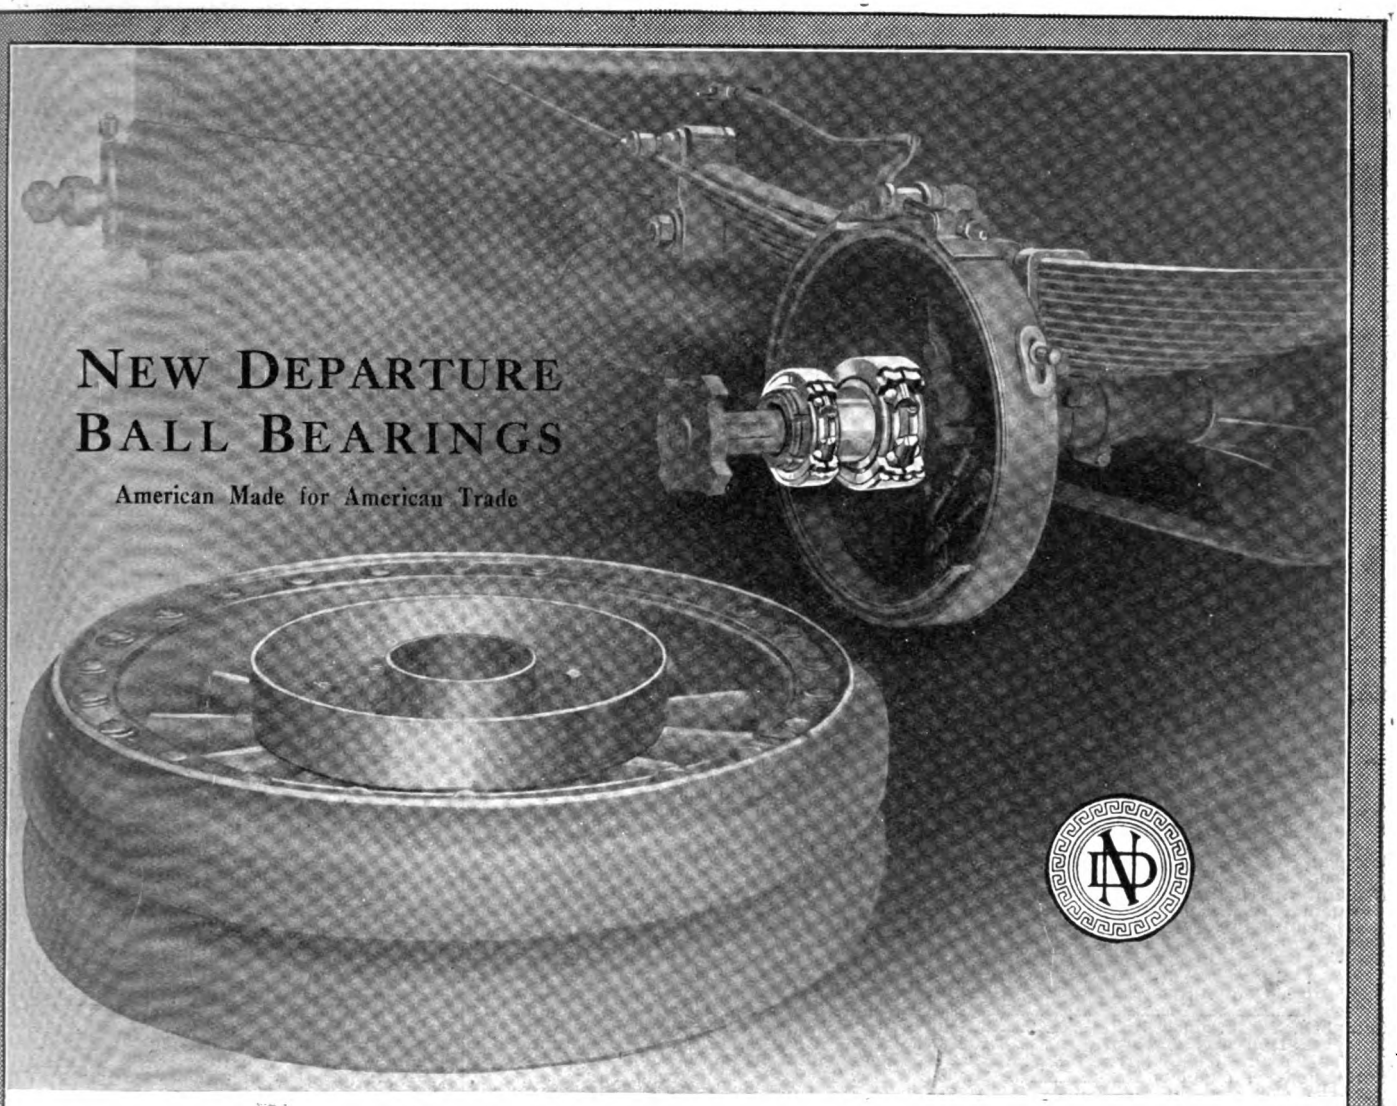
By the new Minnesota law an owner of a machine who drives his own car in the transportation of passengers does not need a chauffeur's license. Instead of paying $3, as under the old law, the applicant for a chauffeur's license will now pay $1.50 and $1 annually for renewal of his badge. The applicant for a license will not have to furnish his photograph to be placed on file with the Secretary of State, as under the old system. Men employed by manufacturers and dealers in demonstrating automobiles do not need chauffeur's licenses. If they drive a machine other than their own and the owner of the car or the driver receives a compensation for the service, the drivers must become licensed chauffeurs. Another change is that the owner rather than the machine is registered. He may change the license tags from one machine to another, and is responsible for this number wherever placed.

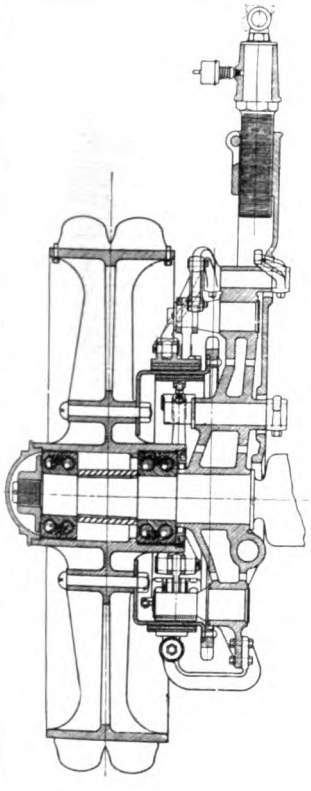
Clifton Spark Plug.

The Clifton Motor Works, 1878 Broadway, N. Y., are offering four of their well-known spark plugs for the price of one. The highest grade of material is used in these spark plugs, they are made in all sizes, and to meet all requirements.

No More Rattling.

The rattle of an automobile door, or of anything else about a car, for that matter, is extremely annoying. The rattling door may be quickly stopped by the





Gouin Anti-Rattler.

use of a new device called Gouin's Anti-Rattler. It is made by L. J. Gouin Company, 14 Roosevelt Ave., Poughkeepsie, N. Y. It can be applied in a minute or two. Its cost is trifling and it is sure to absolutely meet the requirements. Car owners and car drivers as well, will welcome this new appliance. And remember it will stop the rattling of a window as well. It is death on rattles.

Digitized by Google

IN every big motor truck, the five tons or more of load, plus the great weight of the vehicle itself, must be carried on the wheel bearings. More than that, the shocks, the grinding pressures, the numberless strains, stresses and jolts due to rough roads, to change of direction and side-sway, to the use of solid tires and to overloading, combine with weight of car and load and focus at the wheel hubs, thus imposing tremendous burdens upon the bearings.

Compared with other types, the New Departure Double Row Ball Bearing is vastly superior for installation in heavy truck axles because it accepts successfully all of these loads and stresses, either radial or thrust, regardless of the angle from whence they come, doing its work with a lower coefficient of friction than does the conventional type of plain or roller bearing in similar service. The new Departure Double Row Bearing is non-adjustable, hence independent of trouble or damage due to inexperience in handling and the quality of its materials assure a service-life, practically equal to the life of the truck itself.

The rear wheel mounting here shown is ideal for heavy truck work. The inner bearing is clamped to take radial and thrust loads, singly or in combination, while the outer bearing, outer race, is allowed to float and sustains its just proportion of radial load only.

Our Catalog describes and illustrates the complete line of New Departure Ball Bearings and contains besides, comprehensive data covering their practical application and care. Send for a copy.

The Simplex Steam Vulcanizer.

This is an excellent vulcanizer for garages and repair shops. The manufacturers state that this machine will vulcanize 18 tubes and one casing every hour and it is particularly economical as one gallon of gasoline will do ten hours' work. The Simplex carries a sheet of water between the fire and the tire making a damp heat which cannot burn your tires. Complete instructions are furnished with the machine, showing just how to do the work, and this vulcanizer is especially adapted for use in small repair shops as well as in the largest garages where prompt service is required. Any readers who are interested should write for catalogue and prices to the Simplex Tire Repair Company, 2042 Farnham Street, Omaha, Nebr.

Advertising Rates in THE AUTOMOBILE DEALER AND REPAIRER made known on application

JOHNSON'S PREPARED WAX

"Makes Old Cars New Motor Stars"

An application of Johnson's Prepared Wax to the body, hood and fenders of automobiles, electrics and limousines, whether old or new, is a good investment of time. It preserves the varnish and protects it from the weather—it covers up small scratches and minimizes the labor of keeping cars in good condition. Mud spots can be easily and entirely removed from cars which have been polished with Johnson's Prepared Wax. One of its greatest advantages is the fact that it

Does Not Gather Dust

Johnson's Prepared Wax is universally used for polishing floors, linoleum, woodwork, furniture, pianos, etc. It has just recently come into prominence as an automobile body polish and is giving unqualified satisfaction everywhere for this purpose. The Wax imparts a perfectly hard, dry, high gloss which holds its lustre indefinitely—is clean and easy to use—and

"Sheds Water Like a Duck's Back"

Where the varnish has become rough, a perfectly smooth, new body can be built up with Johnson's Prepared Wax. Apply several coats, polishing each well and allowing a half-hour interval between coats. In many cases, this will save the expense of having cars revarnished.

Hood and Fenders

can easily be kept shiney and new looking—an application of Johnson's Prepared Wax after every third or fourth washing will do the trick. Easy and inexpensive.

Agents wanted to sell Johnsons Prepared Wax.

Send us the attached coupon together with 10c in coin or stamps and we will forward postpaid a can of Johnson's Prepared Wax—sufficient for one application on a large car.

I enclose 10c for a Universal Size can of Johnson's Prepared Wax—sufficient for one coat on a large car.

Tires

DOUBLE TREAD
YOUR OLD TIRES

Why not reclaim your old worn out or rim cut tires and have from

2,000 to 5,000 MILES MORE USAGE?

Send us two old tires, one with a good bead, the rubber could be all worn off, and the other with a good tread but can be all rim cut or blown out on the side, and we will combine them into a sound one by our

DOUBLE TREAD RECLAIMING SYSTEM

For a cost of from $2.00 to $4.00.

If you have only one tire in this shape we can furnish you with the other one at a cost of from $4.00 to $9.00. If you have no old tires to have remade you can purchase ready remade ones that we carry in stock. All sizes, from $4.00 to $12.00.

Size	Plain	Non Skid	Size	Plain	Non Skid

Little Giant Grease and Oil Gun.

The manufacturer states that this is a gun which you can load and shoot without mussing or fussing. The No. 1 capacity, weighing 2½ pounds, sells for $5, and the No. 2 gun, weighing 16 ounces, is priced at $3.50. See the Little Giant gun at your dealers, or write direct to the manufacturers, the Neiman Machine Works, Freeport, Ill.

Individuality in Motors.

We have received from the Continental Motor Manufacturing Company, Detroit, Mich., a little booklet of unusual interest entitled "Motors Plus Individuality." It tells of an ancient artificer in iron and steel who manufactured a surpassingly good sword which he presented to the king and then draws a comparison between this admirable piece of work and the Continental Motors which the manufacturers pronounce "superlatively good." We understand that one of these little booklets will be sent without charge to any interested reader who writes for it and mentions the Automobile Dealer and Repairer.

A Good Garage Book.

Mr. A. L. Dyke of St. Louis, Mo., of Dyke's Automobile and Gasoline Engine Encyclopedia, has added 96 new pages to book. Many new subjects are treated. It also includes a simplified treatise on all the 1915 electric starting, generating and lighting systems. This book now contains 1,200 illustrations or 334 full-page charts, 732 pages and 46 instructions. The further description of this book, together with the price, will be found in our advertising columns.

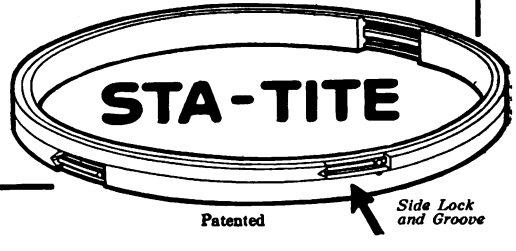
Efficiency Ed

"Piston Rings Are to a Motor What Jewels Are to a Watch."

—Efficiency Ed.

STA-TITE Piston Rings give perfect Compression—cut Carbonization to a minimum, and offer a way of getting highest possible Power from your fuel supply.

Their six points of contact make them resilient and flexible,—make expansion equal and absolutely stop all leakage.



Used on Ported Engines without Pinning. Rings in all Sizes.

Special Inducements to Dealers and Jobbers.

Write for Particulars.

Interesting to Inventors.

Undoubtedly there are many readers of this magazine who are engaged in experimental and inventive work. The Eagle Manufacturing Company, 1831 Blue Rock Street, Cincinnati, Ohio, makes a specialty of doing work for inventors. They manufacture special machinery and patented metal specialties of all kinds. Also electric articles, hardware, etc. They do a great variety of work, including milling machine work, metal spinnings, castings, plating of all kinds, enamelling, japanning, tinning and blue print work. Those who are interested should send sample for expert advice, also for free book containing useful and valuable information.

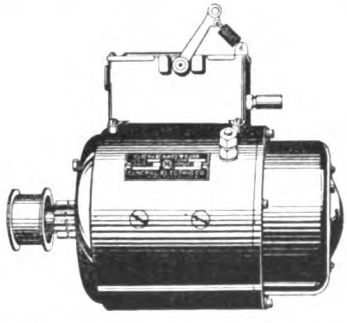
It took 90 Days to Dominate the Field

90 days ago, the market offered over 20 starters for Fords.

90 days ago, the GENEMOTOR was hardly known outside the engineering sanctum of the GENERAL ELECTRIC COMPANY.

Today it is known wherever Ford cars are sold.

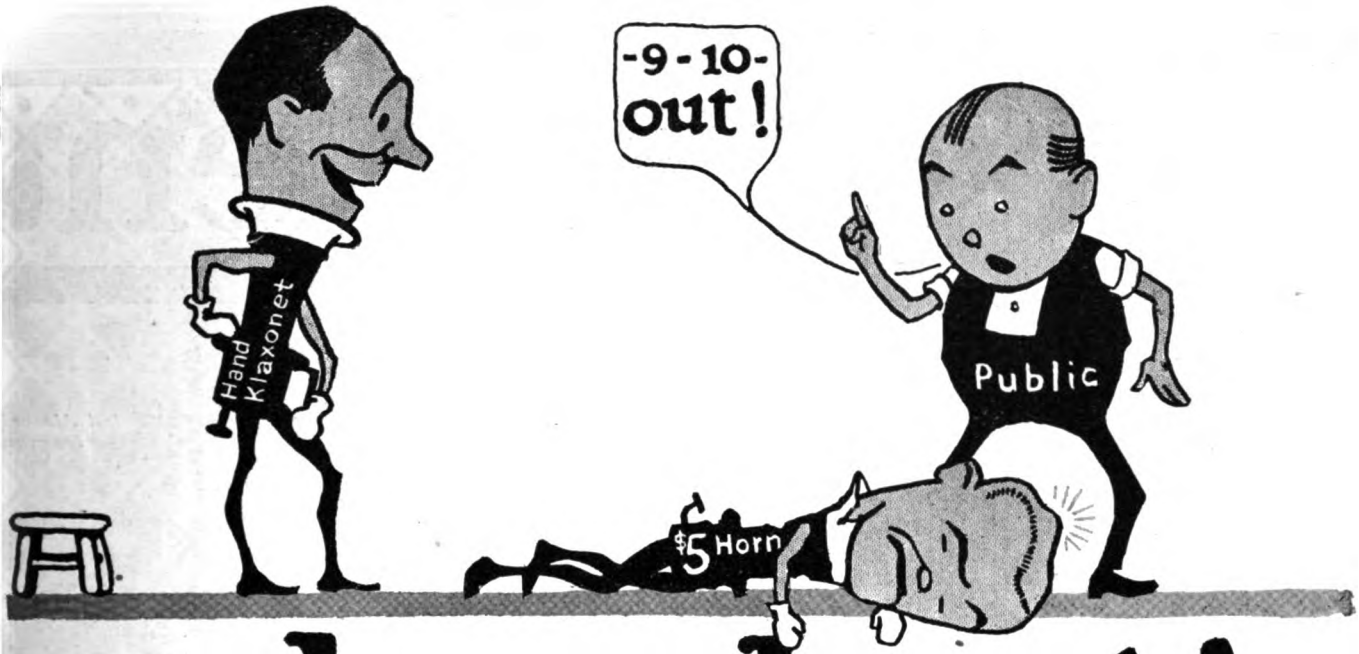
Today it is the fastest selling starter for Fords.



Today the GENERAL ELECTRIC COMPANY is shipping more starters for Fords than all other manufacturers combined.

Today the GENEMOTOR commands the field — dominates it.

In 90 days' time it has assembled through sheer merit, the strongest and ablest group of accessory distributors in America. These distributors form a vast, nation-wide jury. They weighed the evidence of more than 20 starters for Fords, and rendered a decisive verdict in favor of the GENEMOTOR.



A. J. Picard & Company, *Sole Distributors*,

Atwater Kent

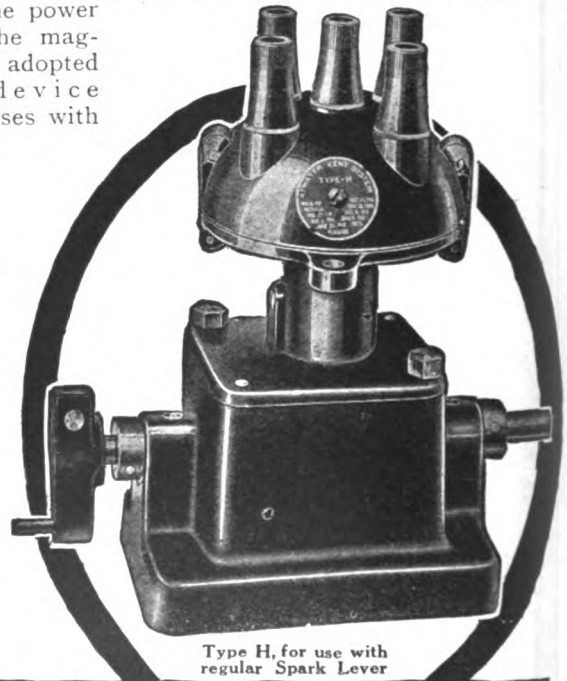
Type K-2
Automatic
Spark Control

John Scott Medal awarded by the Franklin Institute

to A. Atwater Kent for improvements in ignition devices.

MAGNETO REPLACEMENT

TO meet the demand of car owners and dealers wishing to bring their cars up to date and to replace their magneto with Atwater Kent Ignition, we are now furnishing our Type K-2 System with automatic spark control and our type H System (for use with regular spark lever) mounted upon a universal Magneto Base.



By means of this arrangement the Unisparker may be easily installed in place of any standard magneto.

Owing to the fact that this system requires but a small fraction of the power needed for the magneto, we have adopted a coupling device which dispenses with the necessity for special couplings and fittings.

The car owner who has put up with the limitations of magneto ignition can not only improve the starting and slow speed qualities of his car, but can enjoy all the advantages of automatic spark control, flexibility and better acceleration now being experienced by a hundred thousand other enthusiastic Atwater Kent users.

When your car is Atwater Kent equipped you have the satisfaction of knowing that money can buy no better ignition equipment—and that your judgment is upheld by a large number of the foremost automobile engineers in the country.

Used as regular equipment by one-quarter of all 1915 U. S. A. built cars exclusive of Fords.

Type H, for use with regular Spark Lever

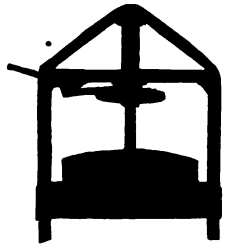
pay for it in THIRTY DAYS

Forcing Transmission Gears.
Forcing Fly-wheels from Crank Shafts.
Pressing Piston Pins in or out.
Pressing Bushings on Connecting Rods.
Forcing Starter and Generator Gears.
Pressing Ball Bearings in Wheels.
Forcing Ball Bearings from Crank Shafts.
Straightening Rear Systems.
Straightening Frames.
Forcing Hubs in Wheels.
Straightening Shafts.
Straightening Axles.
Forcing Drive Shaft Gears.

With Vice Block Attachment



Holding Differential Housings and other awkward work.
Holding Pipes and Rods for Cutting Threads.
Holding Axles and Shafts against twisting strain.

WEAVER GARAGE PRESS

20-TON CAPACITY

THE time and labor you are now wasting with improvised methods in **Forcing Gears and Ball Bearings, Strengthening Axles, Pressing Hubs, etc., etc.,** will pay for a Weaver Garage Press in thirty days.

This Press will also attract to your shop the difficult and delicate jobs which other shops are not equipped to handle.

Designed for Garage Service

This Press is built to accommodate all classes of garage work. Note that it has sufficient width to permit it to receive the largest automobile wheel for pressing hubs, bearings, etc., in or out. (See cut.)

Crank Shafts and similar **Bulky** pieces may also be readily handled by reason of the divided bolster as shown herewith.

Wonderful Leverage

The lever construction supplies a leverage of 1500 to 1 so that the maximum pressure of 20-tons can be developed by one man with ease.

Construction

The frame is of one piece of heavy 5-inch channel steel; hand wheel is 15 inches in diameter, carried upon ball bearings. The thrust of the screw is directed against heavy bronze thrust bearings. The screw does not revolve. Width between frame 32 inches; height of frame 74 inches; floor space 36x36 inches; weight crated for shipment, 450 lbs.

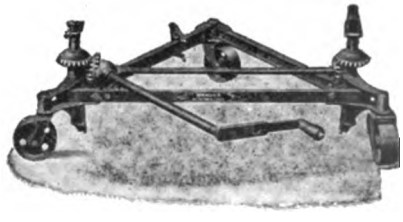
Net Price, $48.00

WEAVER AUTO AMBULANCE

"FOR CRIPPLED CARS"

No repair man need dread the task of "pulling-in" a disabled car if he is equipped with this simple but scientifically designed Auto Ambulance.

A Weaver Auto Ambulance, one man and a runabout, can accomplish a task in half an hour which would ordinarily require three men a half a day to perform without this equipment.



Quickly attached to either front or rear axle of the car, full range of adjustment to meet all conditions; high, broad, CAST STEEL wheels, will stand the service on the city pavements or country roads. Telescoping tongue of double strength steel tubing, roller bearing 1¼-inch steel axle; weight 140 lbs.

PRICE (complete) $30.00

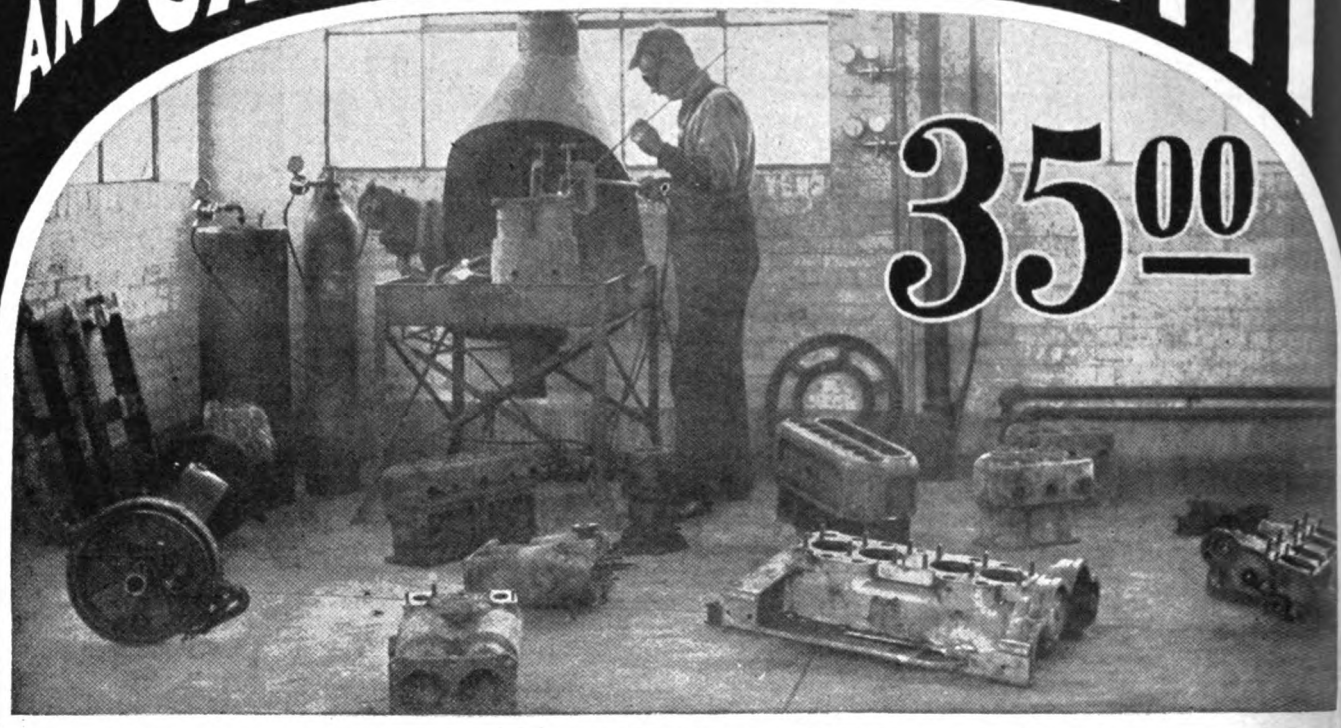
WEAVER AUTO TWIN-JACKS

No Garage, Paint Shop, Repair Shop or Storage Room is complete without an equipment of these combination Turn Tables, Lifting Jacks, Transporting Trucks and Tire Rests. Each Set will save one man's time and 50% of the floor space.

Ball and Roller Bearing Casters and Lifting Mechanism; will apply to either front or rear axle of the car; safe screw hoist; enormous lifting leverage; convenient to handle.

MADE IN TWO SIZES

Regular Type, capacity ..... **4,000 lbs.**
Per Set (Two) $20.00
Singly (As shown above) $12.00



Extra Heavy, capacity ..... **8,000 lbs.**
Pet Set (Two), $36.00 Singly, $20.00

OXY-ACETYLENE WELDING AND CARBON REMOVING OUTFIT

35.00

Guaranteed Suitable for any Welding Job That is at all Practicable. This Outfit Has Just as Wide a Range as the Highest Priced

A few of the many different jobs it can be used on—

Building up Worn Parts; Straightening Frames, Crankshafts, Axles or Bent Parts; Hardening and Annealing; Brazing; Tightening Loose Rivets; Hot Riveting; Soldering; Expanding Frozen Fits and Carbon Removing.

With this outfit a bent gooseneck of the standard chassis can be straightened in 20 minutes and we estimate that four such jobs will pay in gross profit the cost of the outfit.

Ordinary gas, oil and gasoline heating outfits usually sell for more than the price of a DYER, and the latter furnishes 6300° of heat in a very local flame which is most essential in 99% of heat applications.

Gases are mixed in tip, thereby eliminating any possible danger of flash-backs.

Over 1500 of the different styles of DYER OUTFITS in operation in practically every industry where metals are worked or machinery used is sufficient evidence of their reliability.

Shipped to any point in the United States, subject to examination.

If you have a carbon remover we can furnish apparatus necessary to make a complete welding outfit for $25.00.

Write for Catalogue on Apparatus and Welding Materials.

STYLE D
Outfit Complete Consists of

1 Steel Carrying Case.
1 High Pressure Acetylene Regulator with 150 lb. Line Gauge.
1 High Pressure Oxygen Regulator with 150 lb. Line Gauge.
1 Welding Torch with Knurled Handle.
10 Torch Tips, No. 0 to No. 9.
2 10-feet Lengths of Hose with Connections.
1 Connection for Prest-O-Lite Tank.
1 Pair Goggles.
1 Carbon Removing Gun.
1 Set of Instructions.
1 Can Each, Aluminum, Steel, Brass, Cast Iron Fluxes.
2 lbs. Each; 3/16", 1/4", 5/16" Cast Iron, 5/16" Aluminum and 5/16" Special Steel Wire.

"I Told You Tire-Doh Would Fix It, Dad"

The boy knows what he is talking about—what thousands of grown-up car owners know—what you should know. If you are disgusted with the trouble, inconvenience and expense of tire repairs, just try

TIRE-DOH

Once you try it, you will never take your car out again without a Tire-Doh outfit in your tool kit. Whether an innertube has a pin-point puncture, or a tear as long as your arm, Tire-Doh will repair it. Best of all, anyone can use it—anywhere—on the road—in the garage—without heating—without tools—and the average puncture repaired with Tire-Doh costs less than 2 cents.

When you have made a Tire-Doh repair, you can forget all about it, and be sure that it will stay repaired, for

Tire-Doh Repairs are Permanent Repairs

Tire-Doh is not an experiment. An ever-increasing sale for six years proves that it does the work.

Tire-Doh is not a tire filler, but an innertube and casing repair.

Use it to fill cuts and sand blisters in casings, to keep out the water and dirt that rot and wreck the fabric.

Tire-Doh also mends other articles of rubber—rubber boots, gloves, hot water bags, etc.

WE MANUFACTURE
18 Other Tire-Doh Products
All As Good As TIRE-DOH
Silver Quick
Stop That Radiator Leaking
Day Tire Valve
Nomore Rust Rim Paint
Blac-Namel
Sunshine Metal Polish
Everwear Nickel Polish
Metal-Lac
Renew-O Leather Dressing

GOUIN'S ANTI=RATTLER
FOR AUTO DOORS

"The Biggest Little Thing in the Automobile Business"

Car Owners Have Long Been Looking for this Device

The greatest annoyance to a motorist is the continual rattling of doors.

This rattling will wear your locks and bolts very rapidly, and if neglected will ruin them.

Gouin's Anti-Rattler

Can be applied by anyone in a few minutes, and instantly puts a tension on your door so that rattling is absolutely impossible. They act the same way on the hoods and keep them from rattling. Simply rivet under hood ledge and radiator ledge.

The Biggest Seller in the Automobile Field

Ask your dealer for a set of four, $1.00, or they will be sent direct, providing you send us your dealer's name and your check. Money back if not as represented.

Dealers and Jobbers—Write for our liberal quotations. State and County distributors wanted, some good territory open, but it will not last long, so write at once.

Secure this fast selling article at once.

UTILITY

PRICE $10.00
Complete with
Pneu-Meter

THE ONLY TRULY AUTOMATIC TIRE PUMP ON THE MARKET

The Pneu-Meter installed on the hose line prevents over inflation as well as under inflation. Connect your pump, set your Pneu-Meter at the right pressure, start your engine and forget it.

You don't have to watch your pump—the Pneu-Meter does it for you—when your tire is properly inflated, it becomes a **Safety** blow-off valve, using excess pressure to sound a continuous signal. **So simple a woman can work it.**

UTILITY Jr.

PRICE $6.00
Complete with
Pneu-Meter

PRICE $2.00

WHISTLING PNEU-METER

Sold separately and can be installed on the hose line of any other spark plug or gear driven pumps, garage air tanks, etc.

Absolutely accurate and cannot get out of order. Whistles loudly and can be heard fully a block away, and will continue until the engine stops.

Over and under inflation decreases the life of your tires. This is due to the use of tire pumps which are equipped with ordinary dial gauges and which at the best are inaccurate. This trouble and expense can be absolutely avoided by using **Utility Pumps equipped with Whistling Pneu-Meters.**

Smallest and fastest—simplest and best constructed pumps ever made—**absolutely safe.**

Built of rust-proof bronze, brass and nickeled steel. **LASTS A LIFETIME.**

7', 6' and 5' Long Respectively

The UTILITY Socket Wrench Set

A New Principle With Many Advantages

Has all the advantages of socket wrench sets consisting of fourteen wrenches, with none of their faults. Instant in adjustment. No screws to manipulate, or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench.

SOME NEW FEATURES

Will grasp any nut instantly and requires no further effort to hold wrench in place.

In removing, the jaws hold nut firmly at all times, so it cannot fall or become lost. On the other hand, nut can be placed in jaws and applied to bolt or screw when same is inaccessible to the hands.

Unequalled for use in Garages and Machine Shops, in fact, wherever nuts and bolts are used.

Will take all nuts from 3/16 to ½ inch, inclusive.

Will take all nuts used in auto work.

Will take hexagon nuts, square nuts, wing nuts, cock nuts, and nuts rounded or distorted by use of other wrenches.

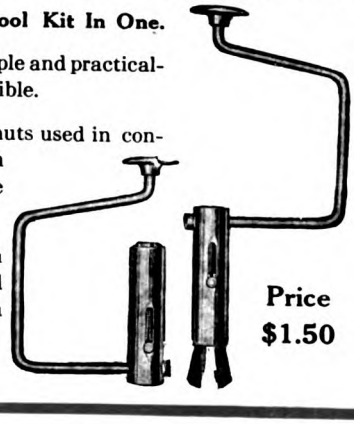
Cannot slip and bruise fingers of workmen, as jaws have rigid bearing on four sides—the harder you pull, the harder the jaws grab the nut.

Look at its wonderful advantages and then look at the price.

Utility Wrench Set Complete, $2.50

Packed in neat canvas bag.

Write for Our Dealers' Proposition.



THE UTILITY DEMOUNTABLE RIM WRENCH

A Whole Tool Kit In One.

Small, simple and practically indestructible.

Takes all nuts used in connection with demountable rims.

Wrench can be folded when not in use.

Price $1.50

A POSITIVE GUARANTY

THE STRONGEST EVER MADE

Guaranty

Every part of the Hoosier Tandem guaranteed absolutely for one year. This includes the contact points. Any necessary replacements will be made, free of charge, at the factory, the user paying simply the transportation charges.

HOOSIER TANDEM MASTER VIBRATOR

Dealers and Jobbers can now assure their customers of continuous satisfaction.

The Only Vibrator Which Cannot Stall The Car By Sticking.

The Hoosier Tandem has TWO PAIRS OF CONTACT POINTS—instead of one, as have all other vibrators.

Sticking points have always been the cause of vibrator troubles—of vibrator-equipped Ford cars stalling.

The heat produced by the sparking of the points is what makes single-point vibrators stick.

It's the tandem points that make the Hoosier different.

No other vibrator has them.

The kick switch has a removable key, preventing tampering with the car.

The case is solid mahogany, highly polished, 7 inches high, 4 inches wide and 3 inches deep.

The Hoosier Tandem points cannot heat to the sticking point—because they alternate the work of sparking. Neither operates long enough at a time to make sticking possible. The two sets of points are constantly automatically relieving each other under service.

Write us now, today, about your 1915 vibrator requirements. We have a proposition that means more vibrator sales and bigger profits to jobber, dealer and garageman.

If you dealer does not carry the Hoosier Tandem in stock, MR. FORD OWNER, order one direct from the factory. We guarantee it to you on a "money back" basis.

The Car Ahead

Pilot

Light Six

PRICE $1885

Pilot Light Six

Weight, 3150 lbs. 126" Wheel Base
63 Horse Power

Condensed Specifications:

Teeter T head motor, bore 3⅞ inch, stroke 5¼ inch, 63 H.P., 16 miles to the gallon of gasoline, 126-inch wheel base, 7/32 inch pressed steel frame with 5-inch channels, 3½-inch flanges. Propeller shaft and universal joints for 90 H.P. car. Warner Gear Co. transmission. Cone clutch. Large size front axle with extra large size roller bearings in front wheels. Rear axle has 7/33-inch pressed steel housing, ribbed and riveted reinforcement. Chrome nickel steel drive shafts 1½ inches in diameter, with flange drive and spline end differential connection. Nickel steel alloy gears in differential with extra large size ball bearings. Rear wheels are carried on double row ball bearings with a guaranteed safety load carrying capacity of 7800 pounds. (We doubt if there is a car in the country that can show such a margin of safety.) Cantilever rear spring suspension. (They will all have them in 1916.) 34x4 wheels. Internal expanding cam brakes. Ventilating Windshield of special design. CENTER CONTROL, LEFT-HAND DRIVE. Westinghouse electric lighting and starting system. Gravity feed. 19-gallon tank for gasoline. Exclusive Pilot dimmer design for headlights. One-man top optional. Quick-acting inside curtains. Foreign design in upholstering. Seven-passenger body with extra size tires $100 additional.

Nothing left to be desired by an automobile owner. A hill climber and a road car BUILT TO WEAR—NOT JUST TO SELL Guaranteed for ONE YEAR.

The Standard Six for 1915

It takes pages to describe the power, construction features, beauty, luxuries and refinements which characterize the above beautiful Light Six. It contains every automobile feature of recognized standard value and many new and exclusive features which in 1916 will be found on many other cars. Its long, racy appearance, its beautiful French streamline body with long tapering hood and special design of radiator, its long running board, its special fender design—give it a distinguished and original outward appearance that cannot but please the most critical car buyer.

Our new Teeter Motor, 3⅞x5¼, 63 Horsepower, makes the Light Six the most powerful Light Six in America.

A study of the accompanying features and essentials will show the mechanic, the dealer and the buyer the most remarkable automobile value ever offered.

SIX CYLINDERS 4½"x6" 132" WHEEL BASE —PILOT 75— 90 HORSE POWER WEIGHT 3850 LBS.

CHAMPION OF THE ROADS AND HILLS

PRICE $2885

A car with power, luxuries, and refinements found only on the millionaire's car. A standing challenge to all stock pleasure cars regardless of size, weight or price, or number of cylinders to a hill-climbing or road contest. If you can afford the price, Pilot 75 represents everything to be desired in an automobile by the most critical buyer.

Care in Purchasing On account of the flood of flimsy, cheaply constructed Light Sixes which are being offered broadcast this year, buyers should exercise great care before purchasing their cars. It's so easy to build a cheap automobile and the buyer unfamiliar with car construction is easily induced to part with his money through a short ride on some boulevard, no criterion by which to judge permanency of service. The agent who in the most glowing terms pictures to the buyer the wonderful car he has to offer at a low price should be asked by the buyer before parting with his money, to sign an agreement guaranteeing free service on the car for a year and then let the buyer make sure that the agent is financially able to back up his guarantee. If the agent is so certain of the intrinsic merits of the car he has to offer, he will sign this guarantee without hesitation. If he does not, do not buy his car. Pay $200 or $300 more and get a real automobile. Keep out of the repair shop and have your car service when you want it. Get some enjoyment from your purchase—not an expense account. Our Light Six circular tells you all about this. Don't fail to send for it.

AGENCY: Let us send you the name of our nearest agency; get a demonstration of road and hill-climbing ability such as you never dreamed of before as possible in an automobile, and if there is no agent in your vicinity, get our proposition for new territory. Our terms, co-operation, and assistance, behind such wonderful cars, insures a successful business for Pilot representatives.

FINALLY SELECTED

By The Engineer

THE BEST PLUG FOR YOUR CAR

Know why we make so many different kinds of spark plugs ?

Because motors vary and the slightest variation often calls for a different spark plug.

The men who built your car might have said, "We'll use the cheapest."

But they did say, "We will have to use the best."

And they didn't take our word for it.

We had to take their particular motor and design and develop a spark plug to get the best results in that motor.

Other spark plug manufacturers were doubtless called upon to do the same.

But the Champion Plug was the final selection of the engineers who represented the builders of your motor

At least such is probably the case, as 75% of all gasoline motors, for every purpose, are equipped by their builders with Champion Spark Plugs.

When you replace your plugs remember that there is a Champion especially designed and developed under severest tests to get the best results in your particular motor.

Your dealer will tell you which Champion to buy.

To accept a substitute is to disregard the most definite expression of scientifically determined expert opinion.

Insist on Champions.

Dealers :—Our 1915 Profit-Sharing agreement is sure to interest you. **Write for it today.**

C-C SHOCK ABSORBER

THIS IS IT

The C-C Shock Absorber for the Ford. Sold with an absolute guarantee of satisfaction or money refunded.

This is the proposition. They must make good or we do not want the money. Thousands of them are in use daily—and they are making good. Why? Because they are constructed of the best material obtainable for the purpose on correct scientific principles—the result of years of experience building Shock Absorbers for all types of cars, from the 1000 pound Roadster to the 5000 pound Limousine. Every feature incorporated in the C-Cs; (steel cushion springs, steel spring cage, grease lubricating bolts, adjustment, rebound spur) is essential, and the fact that it is not necessary to remove the drop-forged steel spring perches from the Ford to attach the C-Cs is sufficient to turn the sale in favor of the C-C Shock Absorbers. In short, they are a quality product at a quantity price. This is only possible through the enormous production. The Ford car can be equipped with C-Cs without removing the wheels.

If you are a live dealer looking for a big selling proposition, write today for folder and discounts.

PAINT YOUR CAR YOURSELF!

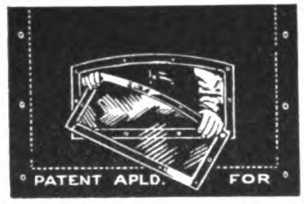
You Can Do It and Save $25.00 to $75.00

Anyone Can Use Our Materials
You Don't Need Previous Experience

FORD SPECIAL OUTFIT is for a high gloss finish in two coats, and is furnished either in Battleship Gray or Black only. Can be applied in an unheated garage. Car out of commission only four days. This outfit includes all materials for repainting Ford T—either touring car or roadster. Together with dressing for top and upholstery and Liquid Gun Metal for lamps, etc. Price complete, $6.50.

ARSENAL VELVET GLOSS is the new dull finish which is so popular for roadsters, toy tonneau and torpedo cars. Anyone can satisfactorily paint a car with Velvet Gloss. Apply a coat today, another to-morrow, and use the car the third day. Velvet Gloss is made only in French, Battleship and Cadet Gray, Apple Green and Ebony Black. No. 1 Outfit, for small roadsters, costs $5. No. 2, for 30 H. P. roadsters and touring cars, $6. No. 3, for larger cars, $7. Top dressings, etc., extra.

THE ARSENAL SYSTEM of repainting motor cars (for novices) should be used by those desiring a high gloss finish. It is in three coats ready mixed for use, together with proper brushes and full instructions. The Arsenal System is made in the following colors: Cadet Gray, Napier Green, Red, Maroon, Brewster Green, French Gray, Battleship Gray, Orange, Cream, Apple Green, Black, two shades of Blue and Brown. There are three sizes of outfits: No. 1, for small runabouts, costing $7; No. 2, for Model T Fords and small touring cars, costing $8, and No. 3 for large touring cars, costing $9. If two colors are desired—that is, the body one color and the wheels another—add 75 cents to cost of each outfit. Hundreds of car owners have saved thousands of dollars by doing their own painting with the Arsenal System.



HOOD AND FENDER OUTFITS. A great many cars have the hood and fenders enameled black regardless of the body color of the car. We make outfits for this purpose in two coats and one color only, black. No. 1 is $2.75; No. 2 is $3.50, and No. 3, $4.00.

ARSENAL LIQUID GUN METAL is the best known brass enamel on the market for lamps, radiators, etc. 50 cts. a can. Pints $1.00.

TOP DRESSINGS for Mohair, Leather, Pantasote, etc., Quarts $1.25, pints 75 cts.

COMPLETE OUTFITS for repainting the chassis only, revarnishing the car, Tire Paint, Body Polish and other materials for improving the appearance of your car.

Replace Your Broken Curtain Light Yourself

THE REPLACE CURTAIN LIGHT is a complete unit and can be installed by anyone without experience. No sewing is necessary, and no tools required. Each light is complete with fasteners for applying. Curtain lights break easily and must be replaced from time to time. If no carriage trimmer is available and a light is to be replaced, the curtain must be taken off and shipped to some repair shop or factory. Heretofore the celluloid lights have of necessity been sewed in the curtain until the REPLACE CURTAIN LIGHT was invented. Now it is only necessary to order the lights from us and you can put them in yourself without taking off the curtain.

Back Curtain Lights for 1912, '13 or '14 Ford touring cars, prepaid, each, $1.50.

Overland touring cars, 1913-14, each $2.50. Others in proportion.

Order a light today and put it in yourself.

NOTE—Patents are pending on the Replace Curtain Light and infringements will be vigorously prosecuted. REPLACE CURTAIN LIGHTS are fully described in our booklet "The Car Beautiful." It is FREE. Send for your copy today.

Our booklet, "The Car Beautiful," describes these materials in detail, and is the only work of its kind published. It tells how to repaint and modernize the old car and how to care for a new one. It's free. Send for it to-day.

S.O.S

Trade Mark Registered

Storage Batteries

No other starting battery now on the market can give the satisfactory service and long life that the S. O. S. battery will give—bar none

Aside from their high voltage maintenance, we guarantee the S. O. S. battery plates **positively will not buckle or sulphate during** the life of battery, under any conditions of use or abuse. They can be **overheated** and **overcharged** and **entirely discharged without injury.**

Dead short circuits will not harm them.

They can stand idle for months without care or attention, and upon being charged will operate to their full rated capacity. They will deliver full rated capacity during their entire life.

They are more nearly fool proof than any other lead plate battery now made.

Any S. O. S. dealer will be glad to make a dead short circuit test for you. Ask him to burn up a 20 penny nail by holding across terminals. Or he will weld a pair of steel files together for you in the same manner. This short circuiting causes ordinary plates to buckle. S. O. S. batteries can be entirely discharged in this manner without buckling of plates. **BEFORE YOU BUY ANY BATTERY INSIST ON THIS TEST.**

CAR OWNERS: The S. O. S. costs no more than any high grade battery. It is positive insurance against battery trouble. Send for our free battery book.

S. O. S. Storage Batteries for Starting, Lighting, Ignition, House Lighting, Railway Signal Service, etc.

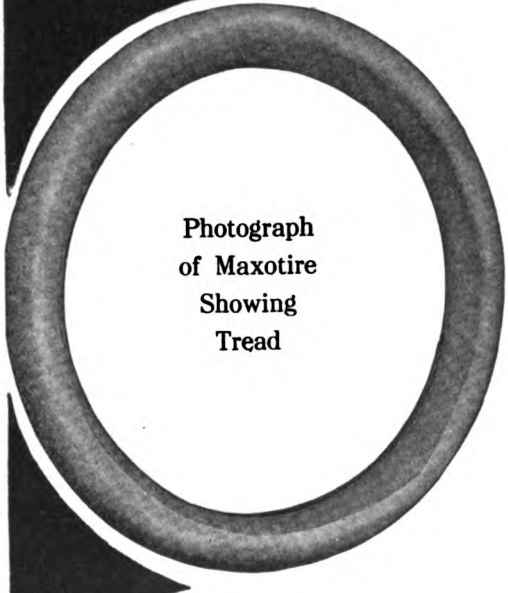
Digitized by Google

Your tires may often be worn down like this without danger of blowout or tire trouble.



You may now run your tires until there is little left of the outside shoe.

The secret of it all lies in the MAXOTIRE which is in reality a perfect tire having a rubber tread, fabric and bead. The MAXOTIRE is so scientifically constructed that it fits the inside of your tire perfectly. It leaves ample space for your inner tube and protects it from being damaged in any way.

The layer of very tough rubber covering the tread surface of the MAXOTIRE acts as a cushion between the MAXOTIRE and the outside shoe.

When the tire strikes a stone or is put to any great strain, this elastic rubber between the two fabric bodies of the tire and the MAXOTIRE equalizes the strain of both and prevents fabric breaks as well as blowouts.

·MAXOTIRES·

Photograph of Maxotire Showing Tread

Nothing like the MAXOTIRE has ever been sold before

Rubber-treaded MAXOTIRES make your tires practically puncture-proof. Tacks cannot reach the tube, while spikes or nails are invariably turned aside.

When MAXOTIRES are placed in tires this tough rubber tread comes in contact with the inner surface or fabric of the tire. This rubber tread clings to the tire like an overshoe to the sidewalk. There is, consequently, no friction; no heat generated; and no chance for the MAXOTIRE to slip and injure the inner tube.

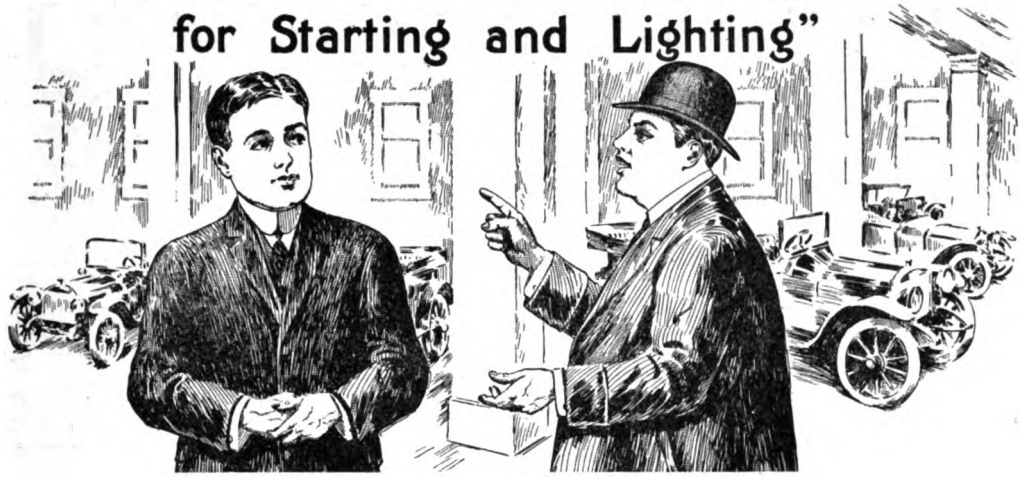
Smaller inner tubes are not required for use with MAXOTIRES; however, they can be used with success at a saving to you of about 25% of their cost.

USE MAXOTIRES

HAVE TWO TIRES PROTECTING YOUR INNER TUBES

Take No Chances This Spring. Equip your tires with MAXOTIRES before taking your car out. While your car has been standing idle during the **winter,** your tires have deteriorated. They are in much worse condition than the outside appears. Tires blow out in nearly every case before the tread is hardly worn. This is due entirely to internal weakness which no one is able to discover.

MAXOTIRES will make your tires **trouble proof** during the coming season and enable you to get the full wear out of every tire. They are not an experiment but the result of seven years' experimenting by the people who invented the first reinforcements for automobile tires.



AUTO OWNERS: See your dealer, he may have MAXOTIRES in stock (for many have), however, if he hasn't—write for our complete free illustrated catalog and prices, express prepaid.

"I'LL BUY on condition that you equip with GOULD BATTERY for Starting and Lighting"

WHO HAS THE BEST JUDGMENT, "A" OR "B"?

"A" took the starting and lighting battery that was handed him. Mr. Dealer made a fine profit, but soon Mr. A noticed that his cranking power would die down suspiciously quick. In winter the battery had to be "boosted." Acid crept out and corroded the terminals. One cell wouldn't equalize with the others, and like a weak chain link, pulled down the whole capacity. During the trouble periods, Mr. A found that hand cranking was no lost art.

"B" said "none but a *Gould* Battery goes on my car, even if the cost is a little more." Three years later he was able to conscientiously tell a friend: "My battery still works as well as when I bought it and I've never yet used the crank. Battery troubles simply don't exist with me."

Gould Storage Battery

The question of judgment here is intensely practical.

A good battery is essential to motoring comfort and assurance that your car is always ready.

Batteries built to sell at a price can't be expected to give service. We prefer to build for service—and Gould battery users agree that we do it.

MOSCO SPECIALTIES

FOGG HORN FOR FORD AND METZ Cars

Still going. Still blowing its clear, mellow signal on thousands of cars throughout the land. Some of the skeptics tell us that the electric horn has supplanted exhaust whistles, but we notice that the old reliable FOGG continues to sell. The reason? Because it is the horn located between the engine and the muffler where it gets the full blast of the gas. Also because it has a cut-out in the body so that in buying the FOGG you get two devices in one—a signal and a cut-out.

Price with Cut-Out, $5.00 Without Cut-Out, $4.50

MOSCO (Loose Plunger) Wheel Pullers

Nos. 2, 3, 4, 5 and 6

The New BEMUS TIMER

FORD CAR TYPE

Bemus Timer Patents
Sept. 24, 1907
Dec. 17, 1907
Feb. 16, 1915
Others Pending.

TIMER SHAFT EXTENSION

BEMUS BALL CONTACT TIMER

Every practical man who knows the Ford car recognizes the fact that this short stroke, high-speed engine requires a Timer capable of rapid, snappy action in the making of contacts and yet having durability sufficient for thousands of miles of running without loss of efficiency.

THE BEMUS IS BEST FOR THE FORD *BECAUSE*

CONTACT is made by a hardened tool-steel brush engaging steel balls with short, glancing impacts, both the brush and the balls turning each time so that fresh contact surfaces are continually engaged.

MOUNTING is direct on the time shaft by means of an extension piece. This brings each of the balls equi-distant from the brush. Result—absolute precision of timing.

STARTING is facilitated in cold weather because these contacts do not hold a body of oil to prevent passage of current.

DURABILITY of unlimited extent is due to a construction which eliminates all wear of the insulation. The roller brush is reversible, and when worn on both sides may be replaced by the user together with new contact balls at an expense of a few cents.

10,000 MILES GUARANTEE BACKS THIS TIRE

TRY Brictson Pneumatic Tires at our expense. Don't pay until you are satisfied. At our risk find out for yourself what wonderful service Brictson Tires give—how resilient and easy riding they are. Get rid of punctures, blowouts and rim cuts. Brictson Tires are rut proof, oil proof and gasoline proof. They are sold under a specific 10,000 mile written service guarantee.

Read What One User Says

"Several months before beginning my trip from Detroit, Mich., to Detroit, Fla., I thoroughly investigated tires of several well advertised kinds. I finally decided for my trip that the Brictson was the most economical and durable tire that I could find.

I am daily asked if I have many punctures. I reply that I do not know what a puncture is. I am driving on all kinds of roads under all kinds of conditions and never have a thing to worry about.

I have been on the road since the 8th day of last October, and if all goes well will begin my Florida trip again about October 1st next. I consider the tires worth almost their weight in gold. I would not do without them at twice the price.

W. J. BREWSTER,
August 10, 1914. 236 Jefferson Avenue, Detroit, Mich."

Your Tires Rebuilt the Brictson Way

If the fabric in the tires you are now using is in good condition, we can take them, make them proof against rim-cutting, punctures, blowouts, side-wall breaks, skidding, ruts, oil, and give thousands of miles of additional service.

Sign and send back coupon for full information and details of our liberal Free Trial Plan.

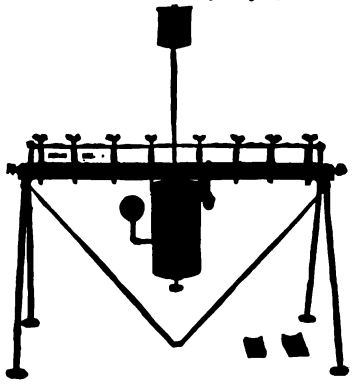
MILLER'S IMPROVED ADJUSTABLE SECTIONAL VULCANIZERS

That repairs everything in the Tire line—all sizes of bicycle, motor cycle, auto and aeroplane tires, also 4 to 6 inner tubes at one time. Made and designed by the man who originated and patented the Cavity Vulcanizer, so generally used throughout the world.

For Steam Line or with Gas or Gasoline Burner } Furnished complete with 28 Bead Molds and 7 Tread Molds.....$95.00 Less All Models.....$42.00

MILLER'S SPRING SPREADER



Quickly adjusted to any width of spring and when adjusted all that is necessary to open up a space between the leaves for insertion of oil is to tilt cam lever.

Many a good automobile has been condemned as a hard rider, simply for the want of oil between the spring leaves. It is a fact, that if the springs are not oiled occasionally that they will rust and stiffen, nearly equal to a solid bar of iron.

Price $1.00

Miller's Inner Tube Vulcanizers
Made in Twenty Styles

Furnished for steam line or complete with Gas or Gasoline Burner, and New Improved Boiler. This Boiler generates an abundance of steam.

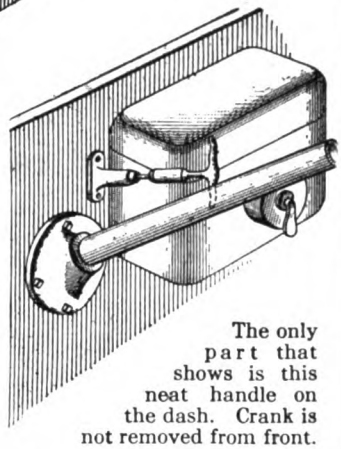
$10 Think of it!

A SELF STARTER FOR 10 DOLLARS

The HUNTER



Complete with all attachments and instructions

JUST WHAT THE FORD OWNER HAS BEEN LOOKING FOR

At Last Mr. Ford Owner!

Your wish has come true. The best starter for a Ford car ever devised and costs less money. It gives you every convenience of the bigger, costlier cars (as you can use electric headlights on your magneto current).

INSTALLED IN ONE HOUR BY ANYONE

The only part that shows is this neat handle on the dash. Crank is not removed from front.

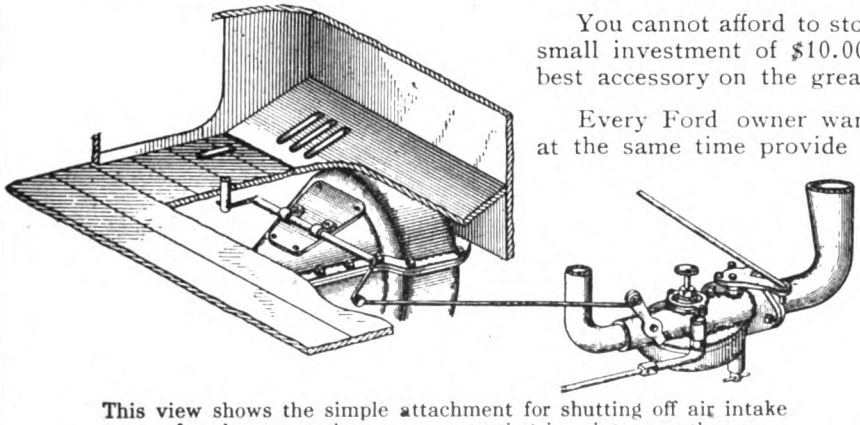
INCREASES THE VALUE OF A FORD THREE TIMES

Note the Advantages

Powerful—The straight pull and powerful leverage enable a woman or girl to start it.

Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.



Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.

You cannot afford to stop at the small investment of $10.00 for the best accessory on the greatest automobile on the market.

Every Ford owner wants to make his car up-to-date and at the same time provide for comfort.

This view shows the simple attachment for shutting off air intake of carburetor to insure easy starting in winter weather.

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. Big money for you in this—the lowest priced reliable Ford Starter made.

HUNTER LOCKS for FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. Price, $1.00. Quickly installed. Sold by leading dealers.

TWITCHELL AIR GAUGE

The Positive Lock Stop
TWITCHELL AIR GAUGE

The Standard Tire Pressure Gauge for 1915

The Best Gauge to Use

Consequently the best gauge to *sell*—

The best way to secure the stocking of your goods by dealers everywhere is to make an article so satisfactory and so perfect that the demand for it will be universal.

Our experience during 1913 and 1914 has convinced us that we are manufacturing such an article in the

Positive Lock Stop TWITCHELL

Both this year and last year, we had difficulty in satisfying the demand.

Don't waste your time and strength trying to push something that is anchored and can't move.

Stock Goods for which there is a demand.

Our advertising in the Trade and National Magazines will be increased this year in order to stimulate this demand still further.

We can make immediate deliveries now. We may not be able to do so in June.

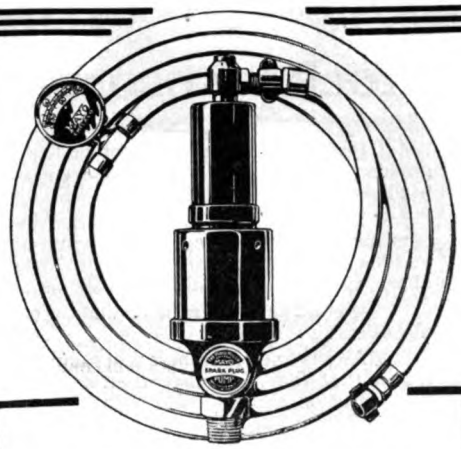
Try One Free On Your Car For 30 Days

If you want the very latest in a permanently attached tire pump, always ready for instant service—install a reliable

MAYO VALVE CAP PUMP



To operate: Without stopping the motor, simply press down the handle, give it a quarter turn and the pump starts working.

Readily installed into one of the valve caps on any 4-cycle motor.

All the unequalled advantages of the MAYO Spark Plug PUMP principle **plus** the permanent attachment feature. No gears to grind and become noisy. Pumps a tire in 3 minutes instead of 10. Complete with 14 ft. hose, gauge and all connections—

$15

None of the disadvantages of gear pump installation and upkeep expense.

If you are touring to the coast this summer or are only driving to the next town—or about the boulevards—you need a

MAYO SPARK PLUG PUMP

—to take care of tire emergencies

A flat tire, with a MAYO to do the pumping, is but a pleasant incident in the drive. Without a MAYO, it is a back-breaking, pleasure-spoiling job, that means pumping 80 lbs. pressure by hand.

The MAYO Spark Plug Pump is the oldest and best known power pump on the market. Pumps pure, fresh air only. Adapted to any car. Instantly substituted for any spark plug. Built with rings like your motor—and lasts as long. Complete, 12 ft. hose, gauge and all connections—

$10

The MAYO is the lowest priced **quality** tire pump. Investigate.

The Pioneer of all Power Pumps —World Famous

Whether you are using your Ford for transcontinental touring this year—or simply touring about home—complete your equipment with a

MAYO FORD PUMP

It takes all the work out of tire pumping.

It gives your Ford the greatest convenience of highest priced cars, and it is a tire economy you can't afford to overlook.

The MAYO Ford Pump is made especially for Ford cars, and as perfectly as the largest MAYO. Attached and operated exactly like standard MAYO Spark Plug Pump.

Complete with 10 ft. hose, gauge and all connections—

$8

The first quality Pump at a price consistent with Ford cost.

You Will Need a MAYO Pump on that Tour to the Coast this Summer

A Sensational Shock Absorber Achievement

A HISTORY MAKING ABSORBER

$10 $12.50 $15

Light Cars Medium Cars Heavy Cars

Designed and priced right at the start to create the largest sales of any such device (as did the Ford manufacturers) and to become the best known and most used shock absorbers.

The NEW ERA Eliptic Shock Absorber for light, medium and heavyweight cars, having simplified construction and handsome design that will appeal to the vast number of owners needing more comfort and desiring to save the car from excessive abuse, yet without paying $25 to $50 for such advantage.

If **good cars** can **now** be had for one-third former price, **Why** not **Good** shock absorbers?

Any user of absorbers will readily state they **are almost** a necessity, and it **is a fact** that they will more than save their cost in a season on **tires** alone, and frequently on springs.

The efficiency of the NEW ERA gives great resiliency and absorption of constant vibration of all small depressions and by its double spiral Vanadium Springs of scientific apportionment and adjustment for the weight of car intended, produced **the ideal** shock absorber at a price all can easily afford to buy.

A most handsome design and rich finish in beautiful black enamel and nickeled trimmed.

Why the High Grade NEW ERA Eliptic Shock Absorber at $10, $12.50 and $15?

Modern designing, eliminating machine work and construction labor, but **one** size, with interchangeable bushings for different width car (leaf) springs and sizes of spring bolts, **and** large factory production, sure to follow at such low selling price.

If the best materials obtainable can be used in the cheapest priced popular automobile **why** not in reliable Shock Absorbers, that the low price will sell rather than immense advertising and added selling expense.

The widest range of cars can be supplied or fitted by dealers with NEW ERA Eliptic Shock Absorbers by the quick and simple change of bushings of different sizes, bolt holes and varying thickness. Sold on a 30-day trial by purchaser, or full purchase price refunded if not satisfactory.

Guaranteed Permanently Against Defects

CAR DEALERS—Don't you want to increase the comfort of your car owner—and your profits? Dealers supplied through most jobbers or us. Ask for nearest one.

Protect your customers and get their good-will by selling

BENTON CASE-HARDENED SPARK PLUGS

Motorists who want something good and appreciate constantly-efficient spark plug service, pick Benton plugs every time if you point out the numerous features explained in our literature.

Briefly, some of these are as follows:

Indestructible wound sheet mica insulator.

Porcelain only a sheath, and could be cracked or even entirely removed without short-circuiting the plug.

Cleaned by unscrewing metal-to-metal gasketed joint, washing insulator with gasoline (or if necessary, scraping with a knife), readjusting points and re-assembling. **Joint always gas-tight.**

Case-hardened wrench surfaces and threads prevent battering.

Spark well out in path of gases and between opposed cylindrical surfaces—ideal for sure ignition, quick cooling and preservation of electrodes.

Semi-circular outer electrode—wide selection for spark gap without disadvantages of multiple points.

Slow to foul and overheat, because little gas gets into the plug, and the shape of inside passages makes exploding gas blow carbon away from insulator.

Liberally guaranteed for life.

Sizes for all automobile, motorcycle, motorboat, aeroplane and stationary gas engine requirements.

PRICE, all sizes, $1.00

Our booklet, "Spark Plugs and How to Make Them Give Perfect Service," would open your eyes to the possibilities from Benton Plugs—a subject which no aggressive dealer can afford to neglect.

Mail the coupon so we can submit our attractive sales proposition and explain why Benton Plugs always make pleased customers.

WALTER L. THOMPSON, 655 W. 43d St., New York

MAKE $250.00 A MONTH

REPAIRING AUTOMOBILE TIRES

Sounds like a lot of money—IT IS—A WHOLE LOT of MONEY to be earning CLEAR every month—yet it's what hundreds of men we have established in the Automobile Tire Repair Business are making. You let down the DRAWBRIDGE for SUCCESS to enter into your career by getting into business for yourself. The business for you is one where the investment is small—the returns quick and for cash—where the margin of profit is large—the demand for your PRODUCT or SERVICE constant and ever on the increase.

A HAYWOOD TIRE REPAIR EQUIPMENT

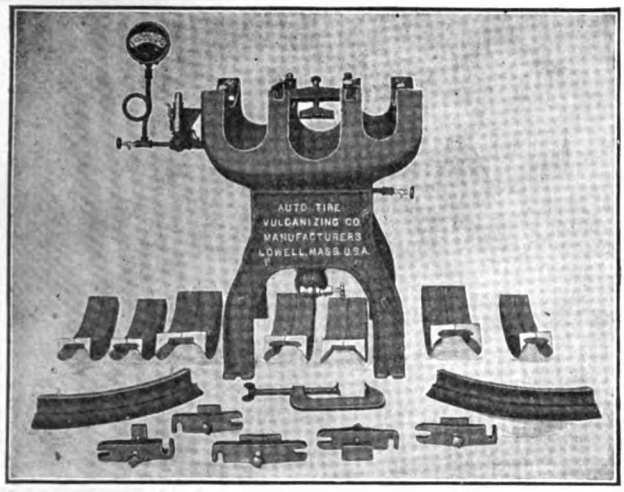
answers to all of these requirements of Old Dame Fortune—the certainty of success in this business is as sure as anything in this world can be—Each year adds thousands of new Automobile Owners—they need YOU to keep their tires in service.

HERE IS YOUR OPPORTUNITY!

Be first to enter this new, big paying business in your town. Open your pockets. Let the dollars pour in. Act quick. Every auto sold means more tires to mend. Automobile business is growing fast—enormous field for tire repairing. Punctures and blowouts are common. Tires need retreading and vulcanizing. Something going wrong all the time. Thousands forced to buy new tires because they can't get old ones fixed. Think of the old bicycle days—repair shops on every corner—all making money—busy day and night. Autos make same proposition over again—only ten times bigger and better. Users of Haywood Tire Repair Plants are making big money. Johnson, Tex., writes: **"I have made as high as $18 in a day."** Another man who bought a plant September, 1911, writes he has **cleared over $3000.00.** That's going some! Operate a plant as a side line in connection with auto business—garage, or as an independent business. Find neighborhood where there's a bunch of autos—get all the steady business besides transient work. Experience unnecessary. You learn quick. Simply follow directions—practice a few days on a couple of old tires and you'll be ready to coin money. Business comes fast and easy.

THIS MAN IS MAKING MONEY

Repair Tires at Home!



Young men and boys! repair father's tires—get money he pays garage man. Get the neighbor's work. Make money to attend college or to start a garage and repair business. **Auto owners**—repair your own tires—save money—pay for your outfit in short time. We have outfits for home use. Anyhow, investigate. Send today for catalogue. See the wonderful possibilities in this marvelous field. Learn of the enormous money-making opportunities in this fascinating new business.

BROWN SUB-BASE OILER
FOR FORD CARS

PAT. DEC. 8, 1914

The hit of the shows. 450 miles on a filling of oil. No pump or sight feed drips—entirely automatic. Can be attached in 15 minutes—no holes to drill. 75 degrees difference in temperature of oil. Less oil and carbon. Cannot flood the motor. Send for booklet on proper lubrication.

Price, ready to attach, $6.00

THE BROWN CO., 100 Bellevue, SYRACUSE, N. Y.

You're Never Cornered with a Starrett Ratchet Wrench

It will turn any standard nut or bolt in all sorts of difficult places—places where the ordinary monkey wrench is useless. For working about an auto, there's no tool like it. The ratchet permits rapid action with only a short arc swing. The extension reaches into otherwise inaccessible places. With this wrench you need never be stalled because of a breakdown that requires a drill, for the drilling attachment furnished with the wrench takes any square shank twist drill from ⅛" to ½" and makes repairs of this kind easy. A reversible screwdriver makes it handy for turning screws of various sizes, too.

Send for catalog No. 20 D C and see the whole Starrett line of fine tools. It's worth while.

BY INVITATION MEMBER OF

Starrett Tools are sold at all good hardware stores throughout the country.

Tuthill
Titanic Unbreakable
Spring

WRITE TODAY FOR

"Best Sellers" Assortment

TUTHILL Titanic Springs

Guaranteed against Center Breakage

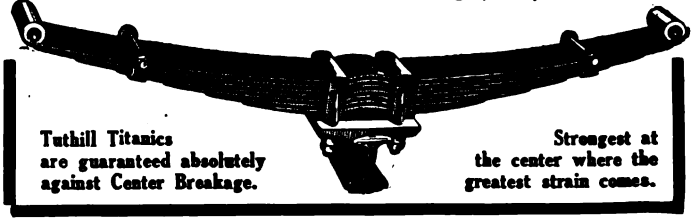
No Center Bolt

If the Tuthill Titanic had a center bolt like the ordinary spring, we would not dare guarantee it forever against Center Breakage – because 75 out of every 100 center bolt springs break in the center.

A Tuthill Patent Device takes the place of the bolt through the center--and a more resilient, longer lasting spring can not be made--it's the spring with no "come backs."

Big stock unnecessary

The object of our Quick Service Department is to make it unnecessary for you to carry an over-stock.

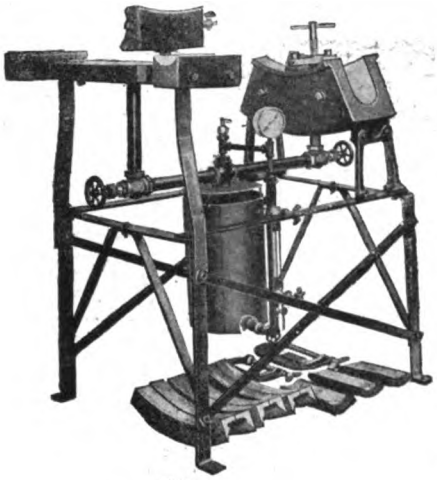


Regular orders shipped same day received—any special orders within 48 hours—enabling you to do a profitable replacement business on a small investment.

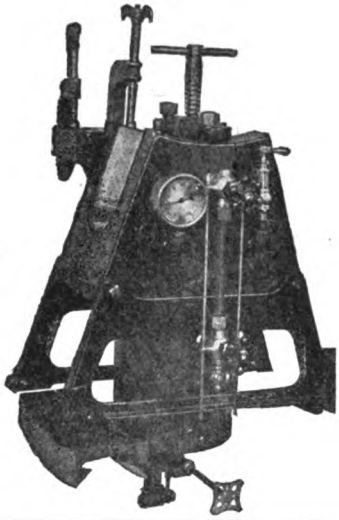
Just wire or write your jobber—or send to us direct. No matter what make or model—there's a Tuthill Unbreakable Titanic for every car.

Tuthill Titanics can be easily adapted to any axle construction and quickly mounted without any extra expense.

TUTHILL SPRING CO.



758 Polk Street Chicago, Ill., U. S. A.



Tuthill Titanics are guaranteed absolutely against Center Breakage.

"NO-LEAK-O"

A Scientific Oil Packing Piston Ring

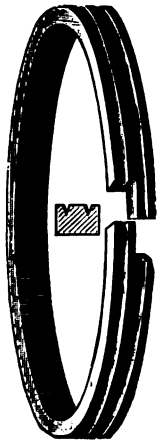
A RING WITH A REASON

There's no mystery about "NO-LEAK-O" rings. A simple, plain, mechanical fact.

Piston movement, uneven expansion and contraction, makes perfect fitting impossible. It's the OIL that forms the seal, prevents escape of gas and lubricates.

It is only a question of how to keep a volume of oil between the rings and cylinder-wall, without waste. There's but one way; that's our way. Make oil grooves around the rings; simple, isn't it?

The grooves convey enough OIL to form the seal, which means perfect compression without WASTE; maximum power with less GASOLINE; perfect lubrication without CARBON, smoke, and oily plugs.



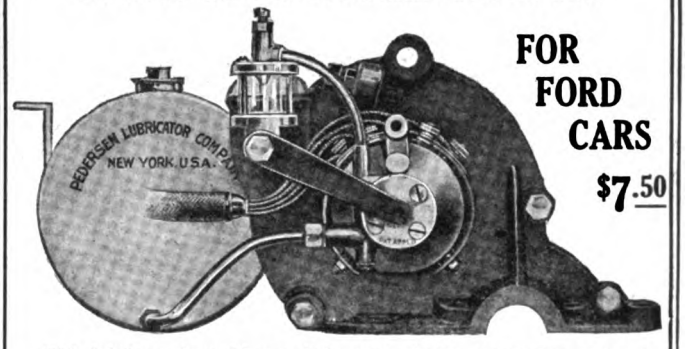
We absolutely guarantee each ring for QUALITY, ACCURACY, and satisfactory service.

One Piece, Low Cost, High Efficiency.

Carbon Eliminated by Controlling the Oil.

AUTOMOBILE ACCESSORIES CO.

816 W. North Avenue Baltimore, Md.



Patent applied for

A NEW FORD CAR

EQUIPPED WITH A

PEDERSEN LUBRICATOR

WAS RUN OVER 6000 MILES WITHOUT REGULATION.
Fill the Oil Tank and the Lubricator Does the Rest.

FOR FORD CARS

$7.50

This lubricator is positive, entirely mechanical in its working and not depending on gravity and pressure. It has no belts, cams or rods to become deranged, but is attached direct to the engine, *starting and stopping with the motor.*

It insures proper lubrication of the motor, with longer life, smoother running, more power and fewer repair bills. It has a half-gallon oil tank, and allows the car to be driven for hundreds of miles with one filling of the tank.

Applied to the car by anyone in 15 minutes.

THE "UNITED TERMINALS"

as illustrated in above cut are the greatest convenience and trouble saver for Ford users. They bring all the wires on top, easy to get at, preventing them from getting oil soaked, twisted or strained at their connections. Should be on every Ford car.

Easily Applied ***Price 50c.***

Dealers write us, you can make money in handling these goods.

REPAIRMEN! MAKE MONEY REBORING CYLINDERS

Pat. 1091318. May 19th, '14.
HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

This tool accomplishes results the same as grinders costing several hundred dollars and a few jobs enables the machine to pay for itself, besides giving the customer service which it would be impossible to give otherwise.

It requires an expenditure of $6.00, and 90 minutes energy to make the cylinders and pistons as tight, true and new as the day they left the Ford Factory. Reboring and fitting oversize pistons is the most important repair that can be given a worn motor, and this is the most important tool you can buy for your shop, for the low price of the tool together with the low price of the pistons makes it an attractive proposition for the repairman who wants to make his shop popular.

Do it now: **The first job of reboring means $ $ $ $ $ to you, if it is done in your shop.**
Write for Full Particulars and Proposition
We furnish the oversize pistons, $1.50 each, net.

Liven Up Your Motor

New or old, it delivers at best less than 75% of the power you pay for. *New or old,* it leaks gas—wastes power—wastes oil.

New or old, you can improve your motor—make it give more power, use less gas, less oil. We guarantee this absolutely—if you equip your motor with

BURD High Compression Piston Rings

Burd Rings are the only 98% efficient rings. They hold Compression no other rings can touch. There's nothing fancy about Burd Rings—no complicated series of interlapping parts. They're just plain, honest, old-fashioned piston rings, accurately made—the kind all engineers endorse. Only Burd Rings have the opening *guarded*—guarded so it can't leak. That's why they hold higher compression—save gas—save oil—give more power. And Burd Rings do the work. They make your motor buck up. They give you power you are paying for, but aren't getting. They save their cost in a few weeks. They are the only Piston Rings guaranteed to do this.

More Miles Per Gallon

"Since installing Burd Rings, my machine gets away quicker, is 50% better on hills, and I must say I get at least 25% more mileage on same amount of gas, and I have watched this carefully."

P. C. CHRISTMAN.

Reduces Carbonizing

"Since putting in Burd Rings, my car uses 60% less oil. During 9000 miles with your rings I have had no trouble with carbon and have never removed a spark plug."

JOHN E. TUTTE.

One-third More Power

"Since putting in Burd Rings, my car has at least one-third more power, and we find that we are saving about 10% on our fuel bill."

C. H. ROSS.

WARRANTY

We warrant every motor equipped with Burd High Compression Piston Rings to produce Higher Compression and give More Power, using Less Fuel and Oil, than when equipped with any other piston ring made, and we will refund the full purchase price of Burd Rings if after 30 Days' Actual Service they fail to meet this warranty. This warranty does not apply to motors having scored cylinders, until after they are reground.

Send for Valuable Book on

"The Why of a Piston Ring."

If you want your motor to give more power, to run on less gas, you ought to have this book. It fully describes Burd High Compression Piston Rings, quotes prices, gives you lots of information you'll be glad to get. Write a postal for it *now*. Book will come free. Address nearest office.

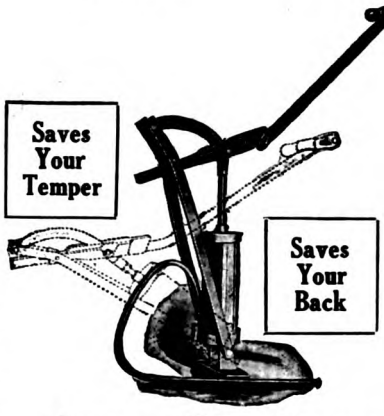
SALESMEN—Some Choice Territory Open for Live Wires.



Which Would You Prefer?

THE BACK BREAKING WAY —OR— THE EASY WAY

Constructed on a principle so practical that even spark plug or engine driven pumps cannot equal it in many cases for convenience of operation. Requires less physical strain and effort to operate than any other hand tire pump made. Does four times the work and four times as easy.

Jensen Tire Pump

No tire pump can equal the Jensen for general economy, simplicity of operation, excellence of results, and durability. A boy or woman can operate it as easily as a man. It does not leak, it has no parts to wear out, and it inflates 90 lbs. pressure with 75% less effort than the ordinary pump inflates 65 lbs. pressure. Every automobilist in the world ought to possess one.

Fits Any Purse—Price $5.00.

There's no such thing as pump trouble where the Jensen Tire Pump is used.

The purchase of a **JENSEN TIRE PUMP** represents the best accessory purchase possible to make.

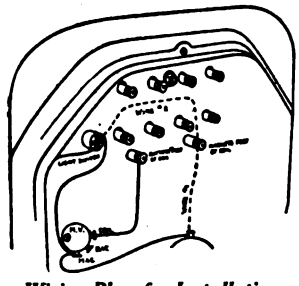
We Manufacture Wrenches Only

MASTER VIBRATOR CONNECTICUT FOR FORD CARS

is the most logical improvement you can make

Recommended Location on 1915 Model Ford Cars.

First: because it gives a Ford motor



MORE POWER,
GREATER FLEXIBILITY,
QUIETER RUNNING—

and it does all of this because it insures a hot spark—a perfectly timed spark.

You should prefer the CONNECTICUT MASTER VIBRATOR to all others, not only because of its superior efficiency, but because it costs less than any other—$9.00—and because its small and compact form affords the most workmanlike installation on your car—an installation so simple that you can make it yourself without calling in an expert.

If your dealer cannot supply you we will send you one, carriage prepaid, upon receipt of price.

Every CONNECTICUT MASTER VIBRATOR is guaranteed by the makers.

Wiring Plan for Installation on 1915 Model Ford Cars

In connecting the coil it will be necessary to run one wire from post marked "Coil" on the Master Vibrator to post marked "Battery" on the spark coil. Then remove wire No. 1 which runs from the magneto to the post on the coil marked "MAG", and bring it around to post on the Master Vibrator marked "MAG". Then remove wire No. 2 running from the lighting switch to post marked "MAG" on the coil and bring it around to post marked "MAG" on the Master Vibrator.

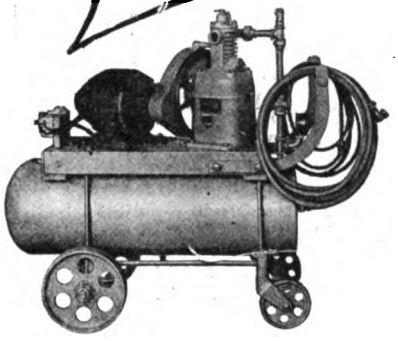
Every Garage Needs One

—You Can't Successfully Meet Competition Without It—



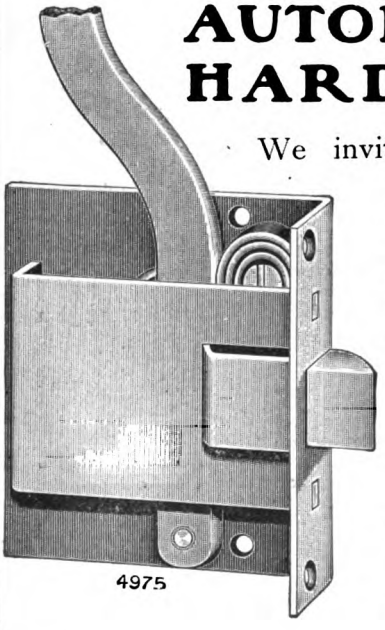
You Must

KEEP AIR ON TAP

Your customers expect it—your prospective customers deal where they get it—then why not put in a

CURTIS AIR COMPRESSOR

Stationary or portable, we can furnish either. Curtis Compressors include many features not found in other garage compressors, for instance:



1. **Will run 100 hours on one oiling.**
2. **Will not carry oil over into the air line.**
3. **Hand unloader permits "easy starting" against any load.**
4. **No oil or grease cups to monkey with.**
5. **Safety cage prevents a broken valve from dropping into the cylinder.**
6. **Die cast bearings, adjustable for wear.**

"STRICTLY A QUALITY PRODUCT"

THE NEW NO. 66 BRUNNER PORTABLE TIRE INFLATOR

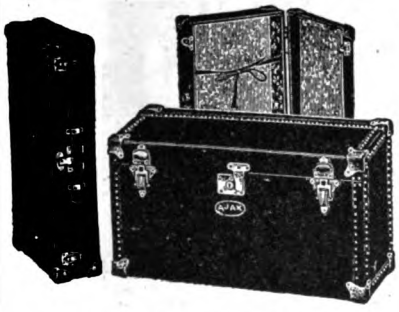
"For public or private garage"

SEVERAL GOOD REASONS WHY THE BRUNNER NO. 66 IS THE BEST SMALL PORTABLE AIR COMPRESSOR MANUFACTURED

First: Because it is the only small portable manufactured that is equipped with a compressor fitted with *three rings on each piston*, and with *GROUND RINGS AND PISTONS.*

Second: Because it is the only small portable air compressor driven by a special *REPULSION-INDUCTION TYPE A. C. MOTOR*, the most expensive and satisfactory A. C. Motor manufactured.

Third: Because the compressor is geared to the motor by means of a *NOISELESS CLOTH PINION* which reduces the noise of operation to a minimum.



Fourth: Because it's a Brunner and can be bought at about the same price as an ordinary cheap outfit of this type.

NO GARAGEMAN COULD ASK FOR BETTER SERVICE OR GREATER VALUE THAN HE WOULD GET IN THIS No. 66 PORTABLE—IT SIMPLY BRISTLES WITH QUALITY.
WRITE FOR COMPLETE DESCRIPTIVE MATTER AND PRICES.

There is a Brunner Portable Electric or Stationary Motor or Belt Driven Air Compressor Outfit suitable for any possible garage requirement, *in stock ready for shipment*, and there is a Brunner "Airtite" Tank or fitting that will improve your service no matter how good you may think it is.

GETTING THE MONEY

REPAIRING TIRES

The biggest money making field in the Automobile Industry today is in **repairing tires.** It is an enormous field and growing larger every year. Locations for good tire repair shops are open in every city and town in the country. You can make

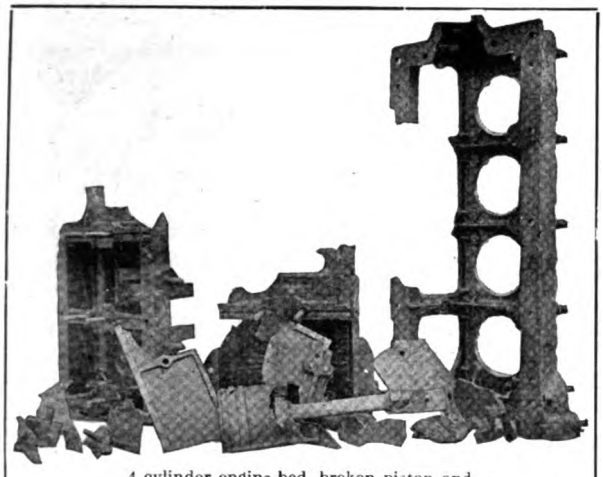
$1500 TO $5000 A YEAR

if you learn by our system of instruction. We teach you every phase of **TIRE REPAIRING and TIRE CONSTRUCTION** by practical demonstration, in a school equipped with every necessary appliance. This is not a correspondence course. You get your training by actually using equipment and repair material. That's the only way.

WE TEACH YOU BUSINESS METHODS

Instruct you how to open your shop. How to take care of sales. How to retain your trade. How to make your shop pay.

WHAT OUR STUDENTS SAY



O. E. Bonnell writes, "I did a $15,000 business last season." **A. A. Robinson,** "Have been in business 30 days. More than doubling expenses. Did not know money could be made so easily." **C. E. Kurtz** says, "We are crowded with work." **C. M. Marsn,** "Business coming too strong, and I have not advertised a bit." Hundreds of others tell of similar successes.

SEND FOR OUR FREE BOOKLET C

It tells all about our school, about our methods of teaching, what our students have accomplished. Be first to enter into this big paying business in your town.

4 cylinder engine bed, broken piston and under side of crank case. Before welding.

Oxy-Acetylene Welding Pays Big Profits to Garage Owners

If you're not equipped to do this class of work in your own shop, you're losing good, legitimate profits.

The welding torch is almost as widely useful as a monkey wrench—almost as handy as an oil can. With it, you can save money for yourself by cutting repair costs. You avoid unpleasant delays, waiting for replacements. The "on the spot" immediate repairs that Oxy-Acetylene welding makes possible more than pleases patrons. Damaged parts can be quickly and easily made good as new at small cost. Most of these repairs would be impossible with any other method.

Even at the most moderate charges, the profits from this end of your business are too big to be neglected.

The daily use of the welding equipment requires that it be simple, efficient, portable and economical in operation. We can furnish this at low cost. We furnish a thoroughly high-grade welding aparatus for $60.00. The average user will also need acetylene cylinders, at an additional cost, and about $10 00 worth of welding supplies. Truck and special equipment for cutting operations at extra cost.

If you use Acetylene for any purpose, you can secure added efficiency and wider scope of operations possible, by using

PREST-O-LITE

Dissolved Acetylene

(Ready-Made Carbide Gas)

PREST-O-LITE Acetylene Service furnishes the highest grade of Dissolved Acetylene in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude acetylene in carbide generators. Besides, PREST-O-LITE Dissolved Acetylene is perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

A Good Business Opportunity

Doing Oxy-Acetylene welding for others is a highly profitable business. The cost of equipment needed is slight. Immense and growing demand assures profitable operation right from the start.

Get Your Share of Welding Profits

Send your name and address on the margin of this page for highly instructive literature on Oxy-Acetylene Welding and Cutting. See what others have done—how you can add to your profits by adopting the up-to-date methods in your shop.

PERKINS APPLIANCE CO.

589 Worthington St. Springfield, Mass.

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,

"Worn Out Tires Made New."

Please mention the size of your tires.

Soak Up the Bumps

with the

FORDEZER

Registered U. S. Patent Office

For improved riding qualities for which they are responsible are little short of wonderful. Their rapid action permits them to absorb—soak up—the vibration that makes long continued riding tiresome even over city pavements. On rough roads the improvement is even more noticeable. The springs are given a chance to act natural—the snappy recoil which is even worse than the downward bump, is entirely eliminated. The saving it effects in tire expense and car depreciation will more than repay their cost in a season.

Made To Fit All FORD Models

Either Touring or Roadster. They are easily applied. Their construction is the best of any Shock Absorber on the market—absolutely dust-proof; entire mechanism covered with a one-piece drawn shell cover, press fitted to the base. Once a year oiling is all that is required for average use. They will outsell and outwear any other Shock Absorber because all supporting parts are drop forged steel and all moving parts bushed with bronze bearings. The flat section, Vanadium Steel springs are guaranteed for life.

Price per set of four . . . $12.00

Manufactured by
WALKER-MOORE MFG. CO.
Racine, Wis.

UNIVERSAL WIRE WHEELS

Constructed of the very best material put together by the highest grade of workmanship.

Hubs are of special steel carefully designed as to weight and contour. They are machined to a perfect fit and may be quickly attached to any Ford hub without filing or cutting and the use of no tool except a wrench. Spokes are finest quality wire spokes—rims of heavy rolled stock, electrically welded and heat treated. Finish is black Japan thoroughly baked on—will not chip or rust.

Price per set, $20.00

SALES DEPARTMENT
FULTON-McCUTCHAN CO., 1508 Michigan Ave., Chicago, Ill.
(Sold through the Jobbing Trade Exclusively)

Make Money Like This Man

He is a garage man and is repairing tires for his storage customers. These cars need to have the tires vulcanized very often and he makes more money from this source than he does from the storage bill or sale of supplies. You can do the very same thing with a

SHALER Vulcanizing Plant

The auto owner, when he comes to you for supplies, gasoline, oil, etc., and knows that you can repair his tires, will gladly give you the job. Give your customers this complete service they like and be ready to repair their tires.

You can easily add $20 to $30 more to your daily revenue without adding to your pay roll.

Anybody who can clean or adjust a car can operate a Shaler, because of the simplicity of Auto- -ic Heat Control and

The Shaler W- -ethod

The Shaler System ha- -many years.

Auto-

This is an ex- -actly at the right po- -ing.

MORE POWER AND A CLEANER MOTOR

Increases Mileage Per Gallon From 40 to 60 Per Cent

Decreases Fuel Cost of Operation In Like Percentage

A money saver for the user.

A money maker for the dealer.

Those who use it come back for more, and so, you Mr. Dealer, can have a steady income from its sale, if you will take up the proposition we have to offer you.

Write for FREE territory selling plans, etc. Also ask for testimonials, letters, or better still order a quart can "GASOLETTE" prepaid (it will treat 64 gallons Gasoline) and convince yourself of its wonderful merits.

Quart Can (will treat 64 gallons Gasoline)..... $1.35
Gallon Can (will treat 256 gallons Gasoline)..... 5.00
Never Sold In Bulk

UNITED PRODUCTS MFG. CO.
219 EAST 22nd STREET Dept. A CHICAGO, ILL.

GASOLETTE

Increases the efficiency of Gasoline without injury to motors.

Gives the motor greater pulling power, more speed and 100 per cent flexibility. sparks quicker and helps the engine to almost instantly pick up and to run smoother.

Prevents pre-ignition, pounding and over-heating of engine.

Removes and prevents carbon deposits on spark plugs, pistons, cylinders and valves, and thereby eliminates engine troubles.

Prevents carbon deposits on exhaust valves and seats, thus eliminating cutting and pitting, and consequent loss of power that can be remedied only by grinding valves.

Prevents carbon deposits on intake valves and seats, which deposits cause loss of compression, loss of power and back firing in intake pipe.

Prevents carbon deposits on pistons, gumming and sticking of piston rings, loss of compression, loss of power—and you avoid the trouble and expense of taking down the engine to clean.

Lessens smoke, odor and noise.

Leaves cylinder and valves in an oily condition and therefore adds life to the engine.

Stop the Blinding Headlight Glare!

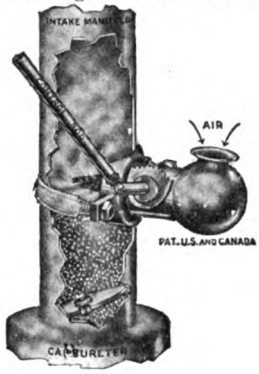
Chaney Automobile HEADLIGHT DIMMER

It enables the driver to graduate the intensity of the light. It can be changed from high to low as you would turn down an oil lamp. Operated by moving the dimmer handle, it gives complete control of the headlights from the seat. In city driving the light is kept low with small current consumption—in the country where full power is needed a touch of the handle brings back the full searchlight efficiency.

DEALERS: Write us for prices and territory.

Manufactured By

THE L. F. CHANEY CO., Springfield, Ohio



Start Right!

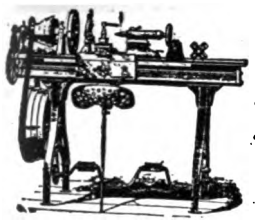
Give your engine a chance this year, to show you what it can do when it is not handicapped by the limitations of your carburetor. *Install a*

MICHENER

GASOLINE SAVER and PRIMER

The MICHENER is easily attached, and requires no change in the carburetor adjustments. It is so constructed that—by a mere turn of the wrist—you *instantly* have the correct mixture for every driving condition. Do you want a rich mixture for starting and heavy pulling? A turn of the handle gives it. Or do you want a lean mixture, for speed, easy running and economy of fuel? Another turn of the little handle, and you have it. In descending grades,—by just a touch—you can open the gasoline saver *full*, which allows the engine to act as a brake. This prevents wear on the brake linings, saves gasoline, cools the engine, scavenges the cylinders, and insures safety in case of accident to the brakes.

You need not take *our* word for it. *TRY IT!* Here is what you will get: maximum engine efficiency, perfect control, and a *GUARANTEED saving of from 25% to 40% in gasoline.* Sold on 30 days' trial. Money refunded if you are dissatisfied.



$5. Dash Control } Insured,
Steering Post Control } Postpaid

When ordering, state side of motor carburetor and steering post are on.

AGENTS! Here is a device that demonstration sells, and that makes a booster of every user. We have some good territory not yet allotted. Write for our agency proposition.

TIRES NEED AIR

Not too much, nor too little—but just enough to keep the tire inflated to the prescribed pressure. There is only one safe, sure way to do this and that is to use a reliable, accurate tire pressure gauge and test the air pressure in your tires frequently. Under-inflation with its rim cutting, loosening of treads, etc., will never bother you if the pressure is tested by the

ALLEN TYROMETER
TIRE PRESSURE GAUGE

This gauge may be used with the valve in any position, and it is guaranteed absolutely accurate. Made of heavily nickeled, specially drawn brass tubing, with sliding band which holds the indication as long as you want it. Only 4½ inches long with clip attached for carrying in the pocket.

ENGINE PRICES DOWN ANOTHER NOTCH!

Look at these Prices!

2 H-P, $34.95; 4 H-P, $69.75;
6 H-P, $97.75; 8 H-P, $139.65; 12 H-P, $219.90.
Other sizes up to 22 H-P, proportionally low.

Direct from Factory to User!

Why pay two prices for any good engine, or take chances on a poor, or an unknown engine, when the "WITTE" costs so little, and saves you all the risk.

WITTE ENGINES, Kerosene, Gasoline & Gas

LET ME send you a "WITTE" engine to earn its own cost while you pay for it. It's cheaper than doing without one. I have proved that to thousands who are now WITTE users.
Ed. H. Witte.

Stationary, Portable and Saw-rig Styles.

Liberal 5-Year Guaranty

CASH OR EASY TERMS.

GET your engine from an engine specialist. All my life I have done nothing but make engines. **The success of my customers and nothing else, makes my success.** I've simply got to sell better engines. I can't lose money on an engine and make back the loss on something else. My factory is the only one, that started in the engine business 27 years ago, which has come through successfully under the same management with which it started. Only WITTE engine-quality has made that possible.

It is cheaper and easier to own a "WITTE" engine than to do without one. My New Offer makes it easier to get the work done by machinery than by muscle or brute power. No need now to get along without a "WITTE."

New Book Free My New Book—the finest in the whole engine business—explains all. It tells you how to be sure in your selection, even if you don't pick a "WITTE." Send me your address today, so I can send you this book FREE with my New Offer.

HOW TO JUDGE AN ENGINE

Important to FORD Owners

The BOSTON STARTER

Is a Time-Tried, Demonstrated Success

The BOSTON STARTER is guaranteed to turn the motor over as certainly as the crank, while the operator is comfortably seated in the car.

The BOSTON STARTER gives the Model "T" FORD CAR the same self-started appearance enjoyed by electrically started cars, at a fraction of the electric starting cost. No batteries, no wiring to require the service of an electrician.

Ford owners—drive right up and ask your dealer or garage man. If he does not happen to know, write our distributor nearest you.

Lighter

1/3 Of Your GASOLINE SAVED BY THE

Economy Gasoline Improver

OR SUPER-CARBURETOR

Cold water will not give off steam, and the best carburetor on earth will not give off real vapor without the assistance of heat, at any time of the year. **Boiling Gasoline** is used at the big races in the middle of the summer.

The Economy Gasoline Improver uses waste heat from the surface of the exhaust pipe to heat the gasoline in the gasoline pipe before it enters the carburetor, greatly increasing the power, improving the running of the engine, decreasing the deposit of carbon and permitting a saving of **One-Third of Your Gasoline. YOU CAN SEE IT SAVE.**

We guarantee that with the **Economy Gasoline Improver** on your car you can turn off the flow of gasoline to the carburetor ⅓ after the engine is warmed up, and still get full efficiency.

PRICE $2.35 **A Special Offer will be made once to each new dealer. Write for it.**

Order through your dealer or direct from us. We ship by insured mail same day order is received. **We pay the postage.**

SEES ALL TELLS ALL

MOTOR EYE

DETECTS MOTOR TROUBLE INSTANTLY

Flashes a warning of danger before the harm has been done. The motor is the car's most costly piece of mechanism and should be given protection commensurate with its importance. A ruined motor means a ruined car. $2.50 invested in prevention may save $100 expended in repair bills.

A radiator thermometer is the only known means for instantly detecting trouble beneath the hood of a running car.

READY TO ATTACH **$2.50**

MOTOR-EYE is the cheapest motor insurance obtainable. Don't pay more for devices that won't do more.

Pin a money order to the attached coupon and get one of these little sentries out on your radiator cap keeping a never-tiring eye on what is going on inside. Money refunded if not satisfied.

Drive Your Ford Over Worst Roads

Gearless Differential for Ford Cars

MERCHANTS
FARMERS
DOCTORS

Must not let bad roads or weather interfere with business.

DEALERS AND REPAIRMEN: You can make big money replacing broken gears with the GEARLESS DIFFERENTIAL. Do you realize that we make the Ford car for commercial use practical now, because we correct the only weak point—the differential gear? Do you appreciate that the Gearless Differential gives a positive drive and brake on both rear wheels, which prevents dangerous skidding, swaying at high speed, stalling in sand or mud, leaving the road, the liability of many accidents, turning turtle, etc.?

Comparative tests show that we save ½-cent per mile to the owner, and pays for itself in first 5,000 miles. It's simple, more durable than gears.

Write for Proposition and Free Circular

Guaranteed Non-Breakable for Life of Car

Complete, ready to install—anybody can make the change in a few hours' time, cost is nominal. Money refunded, no restrictions, if not satisfied within 30 days.

A New Invention
DYKE'S AUTOMOBILE and Gasoline Engine INSTRUCTOR

By A. L. DYKE.

Originator of the first Auto Supplies, Publisher of the first practical book on Automobiles in America.

You learn the PRINCIPLE and CONSTRUCTION of ALL parts of ALL automobiles.

Prepared for the novice, but a handy reference for the expert.

Dyke's Automobile and Gasoline Instructor
Complete **$8.50** (add 60c. to prepay)

It teaches the principle of Automobile, Motorcycle, Marine, Stationary and Aero Engines.

HOW TO REPAIR, ADJUST AND DIAGNOSE TROUBLES
Also covers Salesmanship

Every subject is treated, such as **ENGINES**, with all the different valve arrangements, etc. **CARBURETION**—beginning at the simplest form, to the adjustment of all leading makes. **IGNITION**—from low tension coils to high tension magneto systems. **Care of a Car**; Operating a Car; Lubrication; Building and Equipping a Garage, for home or pleasure; Self-Starters—in fact, every subject is fully covered.

VALUE OF THIS INSTRUCTOR TO YOU

WE CLAIM that with careful study of this instructor, it will enable you to become 1) **AN ENGINE EXPERT** capable of diagnosing ignition, carburetion, valve timing, cooling troubles, and remedying them. (2) **A DIAGNOSIST** who from knowing the principle and construction of all subjects, can instantly tell the cause of any trouble and apply the remedy. (3) **A RUNNING GEAR EXPERT** capable of diagnosing and remedying such troubles as differential, transmission, axles, brakes, steering wheels and axle troubles (4) **AN AUTO MECHANICIAN** who can adjust and remedy all the troubles after diagnosing. The subject of repairing in this Instructor is complete in every respect.

Price of ENCYCLOPEDIA, 600 pages, 1000 illustrations, $3.25 postage prepaid.

FREE—96 page Supplement with 175 illustrations on Electric Starters, Generators, Six, Eight and Twelve Cylinder Engines—with purchase of Auto Instructor.

Digitized by Google

The Most Perfect Piston Rings Made

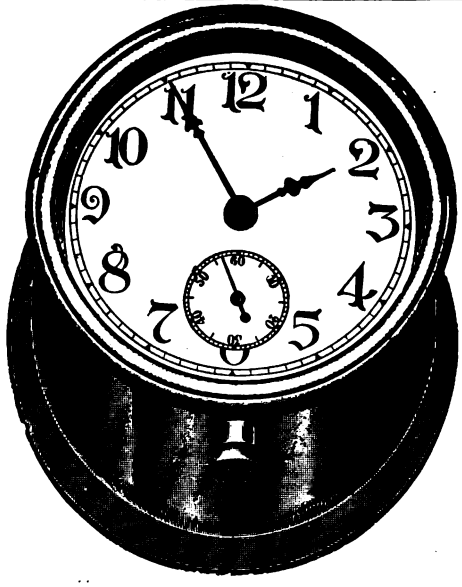
PERFECTION PISTON RINGS

First Operation

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

Last Operation



PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3¾ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

MOTOR VEHICLE PUBLISHING CO.
71-73 Murray Street, - - - - New York, N. Y.

Every Repair Shop or Garage

SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany,** with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

SIMPLE TO OPERATE

BETTER INVESTIGATE AT ONCE.

LEE C. MAPES,

16 Fulton Avenue, ROCHESTER, N. Y.

RAJAH GIANT

The popularity of the Rajah GIANT Plug has increased wonderfully. The present rate of sales shows an increase of more than 300% in a year.

The construction is the same as the Rajah Standard Plug, but it is much heavier in the Porcelain and metal parts.

The Rajah Giant was originally designed for racing purposes, but the general demand for this Plug for motor-boats, tractors, trucks and pleasure cars necessitated adding it to the regular line of Rajah Plugs. Satisfaction guaranteed under the hardest kind of service.

Specially recommended for Cadillac and Pierce-Arrow.

½" and ⅞-18 only.

THE IMPROVED SIMPLEX STEAM VULCANIZER

A TIME SAVER AND A MONEY MAKER—Vulcanizes eighteen tubes and one casing every hour.

ECONOMICAL—One gallon of gasoline does ten hours' work.

SAFE AND SIMPLE TO OPERATE—The improved SIMPLEX carries a sheet of water between the fire and the tire—making a damp heat which cannot burn your tires. Instructions furnished show how to do the work.

ESPECIALLY ADAPTED for use in small repair shops as well as the largest garages where prompt service is required.

Write for Our Catalogue and Prices.

SIMPLEX TIRE AND REPAIR COMPANY
2042 FARNHAM ST., OMAHA, NEBRASKA

K-C SAFETY LOCK PATCH

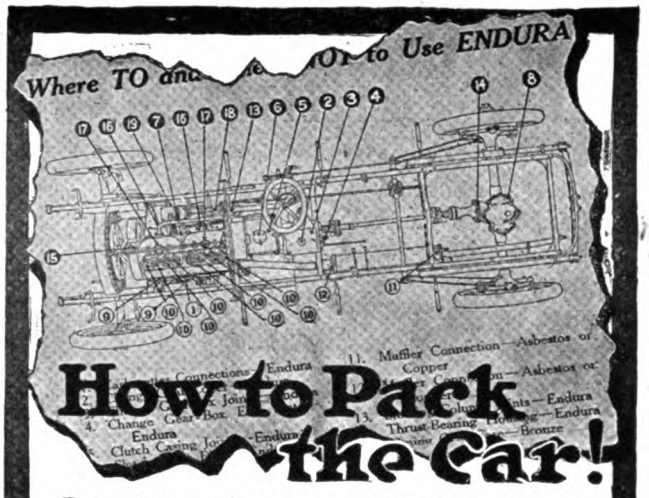
COSTS LESS THAN VULCANIZING!

A vulcanized section costs from $3 to $6. The **K-C Safety Lock Patch** is practically a new section—at one-third the first price and **No Second Cost—No Come Back!**

The **K-C Safety Lock Patch** completely encircles the inner tube. The Lock, formed by edges dovetailing and secured with a wire key, makes spreading or bulging through the blowout hole an impossibility.

Holds the Largest Blowout!

Made of highest quality Tire Fabric. All sizes to fit every make and style of tire.



You might cut away a section of casing from bead to bead and this patch, safely locked in, will hold it's own pressure.

Sold by Leading Auto Supply Dealers and Garages Everywhere.

Price and Quality Must Balance

The quality of the brake lining you sell must be consistent with the price you charge for it, or you will not be able to hold your trade.

This is so—and nobody knows it better than you. That Price and Quality must balance is just as true with respect to net prices as it is with list prices.

What is the Quality of brake linings which list the same as RAYBESTOS—and in some cases higher—but which often are offered you at a lower net price?

What do you suppose is the lowest net price you could get?

How do you know when you get it?

How long before juggled discount prices will affect you?

RAYBESTOS schedule of prices—both net and list—are fixed—uniform to all—and at all times consistent with RAYBESTOS Quality.

Booklet upon request.

Stop —THROWING AWAY YOUR WORN TIRES!—

It's just as unnecessary—just as extravagant—to throw away your tires when they have become tread worn or rut worn as it is to throw away your shoes when the first sole gets thin, for you can get 5,000 miles more service out of them by doing what European motorists have done for the past three years. This will result in a saving of from $50 to $200 a year for you—enough to pay for your yearly gasoline and oil combined!

Don't Let the Junkman Profit at Your Expense

That picture of the junk wagon—with its heap of cast-off tires illustrates in a striking manner what becomes of the average rubber tire after 3,000 to 5,000 miles of service—uncertain service with the ever-present nerve-racking dread of tire trouble.

This waste in tires is distinctly an American extravagance.

What European Motorists Are Doing

The foremost European engineers have for years been studying the problem of getting more miles for less dollars. With their usual painstaking, scientific thoroughness they experimented with leather tire protectors and steel studded Treads.

The result—for over three years European motorists have been "half-soling" their tires with steel studded Treads, just as we "half-sole" our shoes when the original sole gets thin.

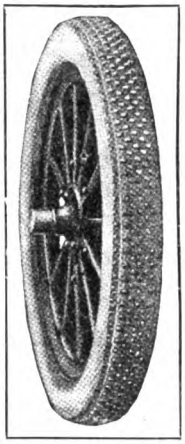
These European motorists are getting from 10,000 to 15,000 miles out of a set of ordinary rubber tires, while American motorists are getting from 3,000 to 5,000, and—what is just as important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim cuts!

Taking Advantage of That European Experience

When we learned that Foreign engineers had perfected a steel studded Tread that would make a tire run at least 10,000 miles, we set about finding out how they did it.

Then we brought to this country probably the foremost German tire engineer, Herr August Bullerman, who designed *Durable Treads* along the line of that foreign study and experiment, improved them by new basic patents and made them even superior to the Treads universally used by European motorists. Their success was immediate. In eight months 20,000 American motorists took advantage of this opportunity to cut down their tire expense and eliminate their tire trouble. Last year the sale of Durable Treads increased 917% in the United States alone. Over 40% of these sales were unsolicited—made through the recommendation of Durable Tread users.

Where is there an automobile accessory which has received such universal country-wide endorsement?



How Does This Affect You?

The almost unbelievable waste in tires by the American motorist is not only national—it is vitally personal. *It affects you—your pocketbook.* Just consider what it would *mean to you* to get 10,000, 12,000, or 15,000 miles out of your rubber casings and at the same time drive your car without the constant dread of tire trouble.

In round numbers it would mean a saving in tire miles sufficient to pay your yearly gas and oil bills—by the elimination of punctures, blow-outs, rim cuts and skidding—a gratification which cannot be estimated in dollars and cents!

Guaranteed 5,000 Miles Without Puncture

Durable Treads are sold under a *signed guarantee for 5,000 miles of wear without a puncture.* This guarantee is an iron-clad agreement—as good as a government bond—and holds good whether your tires are new or old, tread worn, rut worn or rim cut. Think of it—to be able to *FORGET* tires! Not once will you have to get out of that car to fix a puncture, and this *tire vacation* is guaranteed to you!

No More Skidding

Durable Treads are as sure-footed as a burro and they're supremely convenient.

Look at them—they're simply bound to be safe. The sharp-edged steel rivets dig right down through the mud and slush and get to earth every time. They cover the tire completely, extending entirely around from rim to rim. Nothing can work its way in between. They afford a perfect protection—that's why we can guarantee them as we do.

In London and in Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and—what is more important—*you receive perfect non-skid service while your tires are protected instead of injured!*

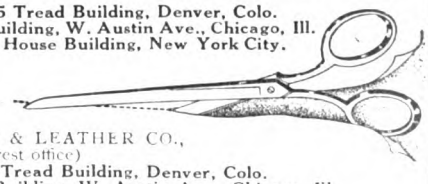
Ask Yourself This Question

Do you intend to continue allowing the junk man to profit at your expense by carrying away in *tire miles* enough to pay your yearly gas and oil bills, or will you turn to your advantage the experience of European motorists?

It is the same question of economy you decide when you "half-sole" your shoes instead of throwing them away when the first sole gets thin. Rubber tires cost several times as much as shoes and are certainly worthy of the same economy.

Special Discount Offer

To motorists in territories where Durable Treads have not as yet been introduced we offer a special introductory discount *equal to the full dealer's profit.*



Will you let us give you a demonstration at our own expense and risk? Will you let us make you an offer so fair and square that you do not stand to lose one red cent either before or after you buy?

The time for action is *NOW*, before the tires on your car run another week in a "barefooted" condition—before you get your next puncture or blow-out.

Cut out the coupon below. If you haven't pen or pencil handy you can fill it out afterwards, but *cut it out now* before you turn the page and forget. It will be the means of adding at least 5,000 miles more life to the tires on your car.

FORD Owners: Have YOU This Kind of Power?

THIS is how your Ford acts with a poor ignition system. Each horse represents a cylinder of your engine, the wagon your car. Instead of pulling equally, as they should, one horse is jerking ahead, another to the side, one backing, and the other plunging in the air. The truck is getting nowhere. It is being wrenched and racked. It is a true example of EXPENSIVE INEFFICIENCY.

Multiunit coil ignition makes your engine pull like these four balky horses; one cylinder pulls powerfully, another barely moves down on its power stroke; each cylinder works against the others. There are vibration, uneven power and overheating. The engine and car soon become racked and ruined.

THE·BOSCH·MAGNETO
The · Modern · Ignition · System

cures all this, for it serves the Ford as well as it serves the scores of high grade cars on which it is standard. It gives power and snap to the engine, because its arc-like sparks ignite ALL the gas in the cylinders and occur in exact relation to each other. It produces even running, the utmost efficiency and a smile of satisfaction. It's like the powerful team pulling together—IT'S A REAL NECESSITY.

You save yourself all ignition worry, you get a better car, you're satisfied when you fit your Ford with a Bosch Magneto. A simple attachment makes it easy. Fill out the coupon and get an inkling how to make your Ford a better car.

Bosch Attachments made also for all Battery Ignited Cars

Bosch Magneto Company
202 West 46th Street, New York

Please send me the "Key to Ford Efficiency" and full information about better ignition for Fords.

New York Uni-Coil Ignition System for Ford Cars

PRICE $15.00

It gives all the advantages of the best high tension magneto service. The spark is delivered in perfect time to each of the four cylinders. No failure is possible at any speed. Greater power, speed and flexibility is attained by its use.

Operated by the Ford Flywheel Magneto or Battery

It increases the efficiency and perfects the timing of the Ford Magneto to a degree that puts it in a class with the best big-car magnetos. The **vital factors** in **magneto efficiency** are all embodied in its construction—a magneto contact breaker, with but one pair of adjustable contacts—an advanced type of high tension distributor that uses but one of the standard Ford coil units.

The New York Uni-Coil gives the Ford the ignition efficiency of the high-priced cars. It permits unlimited spark advance and assures perfect accuracy in timing at all speeds. It greatly simplifies the Ford ignition apparatus, eliminating the timer and practically all the present wiring. It is readily installed on the car, all necessary fittings and connections being supplied. This equipment includes an **elevating gear bracket which is permanently oil-tight.**

The complete Uni-Coil Ignition System costs $15.00 at retail. Dealers' margin is right—selling terms on request.

NEW YORK COIL COMPANY
338-340 Pearl Street **New York**
WESTERN BRANCH: 1461 Michigan Ave., Chicago, Ill.

DEALERS!

The 500,000 Ford Owners of This Country Form a BUYING PUBLIC That You Can't Afford to Overlook—Here Are Two Ford Necessities That Will Bring Their Patronage Your Way.

The New York Master Vibrator, $10.00

Successful for Six Years on Ford Cars

READILY INSTALLED ON THE NEW 1915 MODELS

The "New York" has always led—six years ago Ford owners were enthusiastic about its performance—to-day it is giving satisfaction on thousands of cars, old and new. It was first in the field and has since been imitated many times, but never equaled.

DOES NOT STICK

Requires the Minimum of Attention

The **"New York"** demands less in the way of adjustment and correction than any other type of master vibrator. It practically manages itself. Under all conditions of service it insures a hot, powerful spark, smooth performance and easy starting. It practically eliminates carbon deposits in the cylinders by producing cleaner combustion. Many engine troubles are avoided when the "New York" is installed on a Ford Car.

It pays for itself in the saving of coil replacement expense and in gasoline economy. At $10.00 it is the best "buy" you can offer a Ford owner. Used with our contact points it is good for the life of the car. These are supplied in **sealed red envelopes bearing our name**—the guarantee of quality and efficiency.

NEW YORK COIL COMPANY
338-340 Pearl Street **New York**
WESTERN BRANCH: 1461 Michigan Ave., Chicago, Ill.

What's the Answer to the Mileage Question?

But They Can't Answer Your Mileage Question Unless They're On Your Car

SOME men try to answer this question by buying tires at a price. How can they get mileage out of a tire that price prohibits the builder putting into it? Others endeavor to answer it by dickering for adjustments—and that is all they get. Others accept the factory equipment tires on their cars as the solution to the mileage question. But the car builder neither makes nor guarantees tires.

This mileage question is never settled until it is answered right. You can only get as many miles out of a tire as the manufacturer puts into it.

Miller Builds Mileage *In* For You

by first making a shock-resisting backbone of cotton fabric. And do you know that fabric is just as important as rubber in a tire? In fact, while rubber is necessary for resiliency, its greater function is to protect the fabric. The Miller method, which gives you the right rubber compound (and plenty of it) *goes farther.* It produces the right kind of fabric and that's what makes *Miller Tires go farther.*

The Miller Method is an exclusive process of vulcanizing with a low degree of heat—applied for a short time. It retains the natural wax and oil in the cotton fibre, and thus prevents internal friction, because it leaves nature's lubricant in the minute strands and fibre of the cotton.

This wax and oil carbonize at 240 degrees, but the old method requires 287 degrees to vulcanize the tire. A brittle and lifeless fabric cannot stand the terrific punishment that all tires must endure.

The process by which Miller tires are built, thoroughly vulcanizes, makes a perfect unit of rubber and fabric, without burning the life out of either, and with no point of cleavage in the construction.

This method of vulcanization—the retention of the vegetable wax and oil—means life in the fabric and rubber. It results in safety—freedom from blow-outs, and additional miles of wear in Miller tires, as thousands and thousands of motorists have found out.

Settle this mileage question today by going to the Miller dealer. When he puts Miller tires on your car, you can put the mileage question out of your mind for good.

The answer to the skid question is Miller Geared-to-the-road Tires! They gear your car to the road through mud, sand or slush. **With Miller tires on your car you're in control. Its tread is an integral part of the tire and retains its safety features until the entire tire is worn out.** The greater mileage you get from them will make your choice of Miller Tires an economy, as well as a permanent safeguard.

MILLER TUBES answer the tube question.

Something New in Storage Batteries

The frailty and uncertainty of the storage battery has been the great drawback of the industry. No department of electrical science has offered greater difficulties.

The first great battery expert of the country was Pumpelly.

The basic principles of all successful battery construction today are those developed by Pumpelly thirty years ago.

Three decades of tireless work have been put in since then by Pumpelly. A member of a very wealthy family, he has been able to take his time to perfect his ideal battery.

Many able engineers have assisted him in this development. At last he has achieved his purpose.

A tremendous advance in battery construction is marked by the improved Pumpelly Battery.

Its marvellous efficiency and durability have proved a revelation to the engineers of the biggest automobile factories and electrical stations of the country. They have submitted it to the most searching tests they have been able to devise. As a result—

We have their contracts for batteries. That's fair proof that their astonished praises are not mere friendly words.

Big business is the natural, inevitable result of such a remarkable product. We have prepared for it in three ways—and are preparing for it in a fourth.

Low factory costs mean that this wonderful battery competes in price with the old-type batteries.

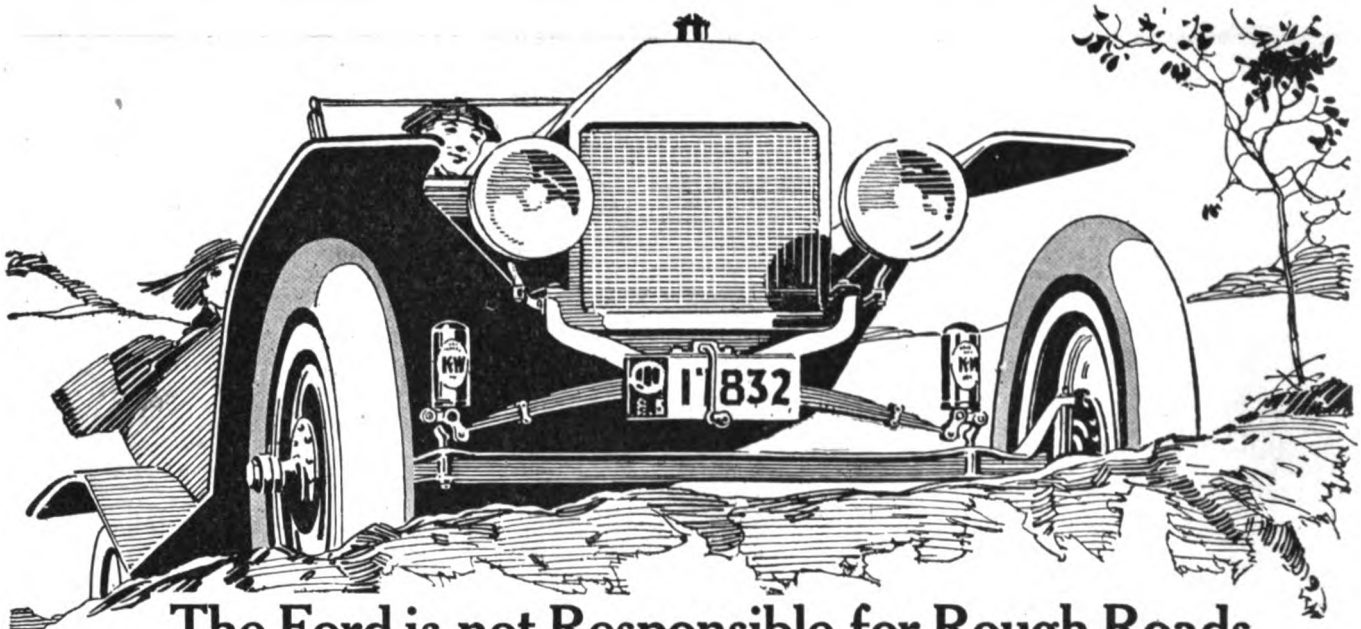
Large manufacturing capacity means **immediate shipment** of your order, whether it is for one battery or for 1,000 batteries.

Batteries for every size and shape of box are kept in stock in ample quantities. You can replace any known make of battery with a Pumpelly and you can have it shipped at once.

We make a battery for every type of starter—a battery for every make of car.

A country-wide Service System is being rapidly built up. We have over thirty service and sales stations now. We want more. That's where **you** come in. You can control the battery renewal business of your town.

You'll do more business and you'll make more money on the volume than you have ever dreamed of.



It's the Big Profitable Business of today and tomorrow—this renewal business. Your experience is beginning to tell you that.

Get in Right on It by writing us today for our special service and sales station proposition.

The Ford is not Responsible for Rough Roads

But no matter how rough the roads or how fast you drive you can ride smoothly over every inch of the roughest roads when you equip your Ford car with

TRADE K-W MARK REG U.S. PAT OFF

Road Smoothers

QUICKLY APPLIED TO YOUR FORD CAR

Give you Ford car advantages, with heavy car comfort

In Buying, Here's What You Must Look For in Order to Combine Comfort, Safety and Economy:

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost *twice the length of spring action* or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

$15 SET OF FOUR ONE FOR EACH WHEEL

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all these vital factors *only* in K-W Road Smoothers.

That is why they lengthen the life of your car, by eliminating shock and vibration. Tire economy is assured, because K-W Road Smoothers enable the wheels (not the whole body of the car) to follow the contour of the road. That means no grinding off the rubber of the tires. K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary, except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your cars' usefulness, and bring you home with "that satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

Write for booklet, "That Satisfied Feeling".

The name Red Elefant marks the spark plug that's right—

rightly designed—rightly built— rightly priced—right in every way!

Take Another Look

Glance again at the types we've illustrated. Don't they impress you as pretty husky plugs that would take their daily punishment without whimpering? Red Elefant plugs do behave most beautifully under all sorts of conditions. *Guaranteed for a year.*

Get Ready for the Demand

We're stirring up a lively business in Red Elefant plugs. You're bound to hear from our advertising in farm papers and automobile magazines. You'll find that Red Elefant plugs no sooner march in on your shelves than they march right out again.

Answer This—

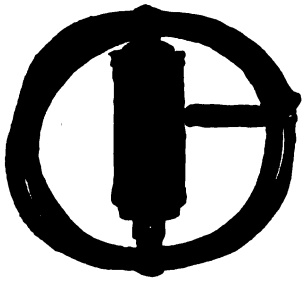
What's the use of stocking 157 varieties of alleged spark plugs when you know very well there are only two kinds—punky plugs and those that make good? Red Elefant plugs are in the front row of the "make-good" brand—and they're not overcrowded for room in this preferred position.

Your Customers Will Say, "Bully Plugs!"

Send us a trial order. Sell your crankiest customer a set. Tell him to give the Red Elefants the third degree of use and abuse. When he reports—as he surely will—"Bully good plugs; give me a spare set"—then you'll send us a nice fat order.

Do we get this "I'm from Missouri" trial? Here's hoping!

Free to Dealers



Having trouble with collections? Here's where we can help you. Let's send you three letters that have proved 90% efficient in getting the money and retaining the customer. Write "Dealers' Service Dept."

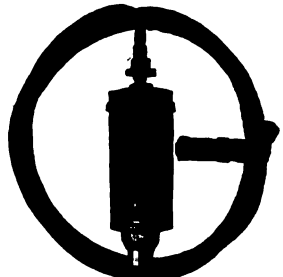
UTILITY

PRICE $10.00
Complete with
Pneu-Meter



THE ONLY TRULY AUTOMATIC TIRE PUMP ON THE MARKET

The Pneu-Meter installed on the hose line prevents over inflation as well as under inflation. Connect your pump, set your Pneu-Meter at the right pressure, start your engine and forget it.

You don't have to watch your pump—the Pneu-Meter does it for you—when your tire is properly inflated, it becomes a **Safety** blow-off valve, using excess pressure to sound a continuous signal. **So simple a woman can work it.**

PRICE $2.00

UTILITY Jr.

PRICE $6.00
Complete with
Pneu-Meter

WHISTLING PNEU-METER

Sold separately and can be installed on the hose line of any other spark plug or gear driven pumps, garage air tanks, etc.

Absolutely accurate and cannot get out of order. Whistles loudly and can be heard fully a block away, and will continue until the engine stops.

Over and under inflation decreases the life of your tires. This is due to the use of tire pumps which are equipped with ordinary dial gauges and which at the best are inaccurate. This trouble and expense can be absolutely avoided by using **Utility Pumps equipped with Whistling Pneu-Meters.**

Smallest and fastest—simplest and best constructed pumps ever made—**absolutely safe.**

Built of rust-proof bronze, brass and nickeled steel. **LASTS A LIFETIME.**

7", 6" and 5" Long Respectively

The UTILITY Socket Wrench Set

A New Principle With Many Advantages

Has all the advantages of socket wrench sets consisting of fourteen wrenches, with none of their faults. Instant in adjustment. No screws to manipulate, or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench.

SOME NEW FEATURES

Will grasp any nut instantly and requires no further effort to hold wrench in place.

In removing, the jaws hold nut firmly at all times, so it cannot fall or become lost. On the other hand, nut can be placed in jaws and applied to bolt or screw when same is inaccessible to the hands.

Unequalled for use in Garages and Machine Shops, in fact, wherever nuts and bolts are used.

Will take all nuts from ⅛ to ½ inch, inclusive.

Will take all nuts used in auto work.

Will take hexagon nuts, square nuts, wing nuts, cock nuts, and nuts rounded or distorted by use of other wrenches.

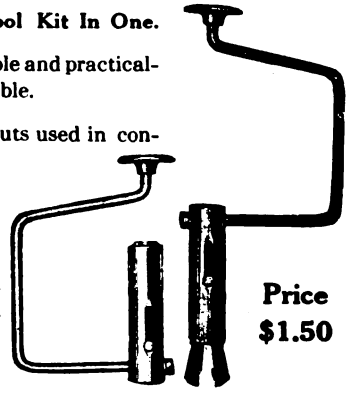
Cannot slip and bruise fingers of workmen. as jaws have rigid bearing on four sides—the harder you pull, the harder the jaws grab the nut.

Look at its wonderful advantages and then look at the price.

Utility Wrench Set Complete, $2.50

Packed in neat canvas bag.

Write for Our Dealers' Proposition.



THE UTILITY DEMOUNTABLE RIM WRENCH

A Whole Tool Kit In One.

Small, simple and practically indestructible.

Takes all nuts used in connection with demountable rims.

Wrench can be folded when not in use.

Price $1.50

MOSCO SPECIALTIES

FOGG HORN FOR FORD AND METZ Cars

Still going. Still blowing its clear, mellow signal on thousands of cars throughout the land. Some of the skeptics tell us that the electric horn has supplanted exhaust whistles, but we notice that the old reliable FOGG continues to sell. The reason? Because it is the horn located between the engine and the muffler where it gets the full blast of the gas. Also because it has a cut-out in the body so that in buying the FOGG you get two devices in one—a signal and a cut-out.

Price with Cut-Out, $5.00 Without Cut-Out, $4.50

MOSCO (Loose Plunger) Wheel Pullers

The New BEMUS TIMER

FORD CAR TYPE

Bemus Timer Patents
Sept. 24, 1907
Dec. 17, 1907
Feb. 16, 1915
Others Pending.

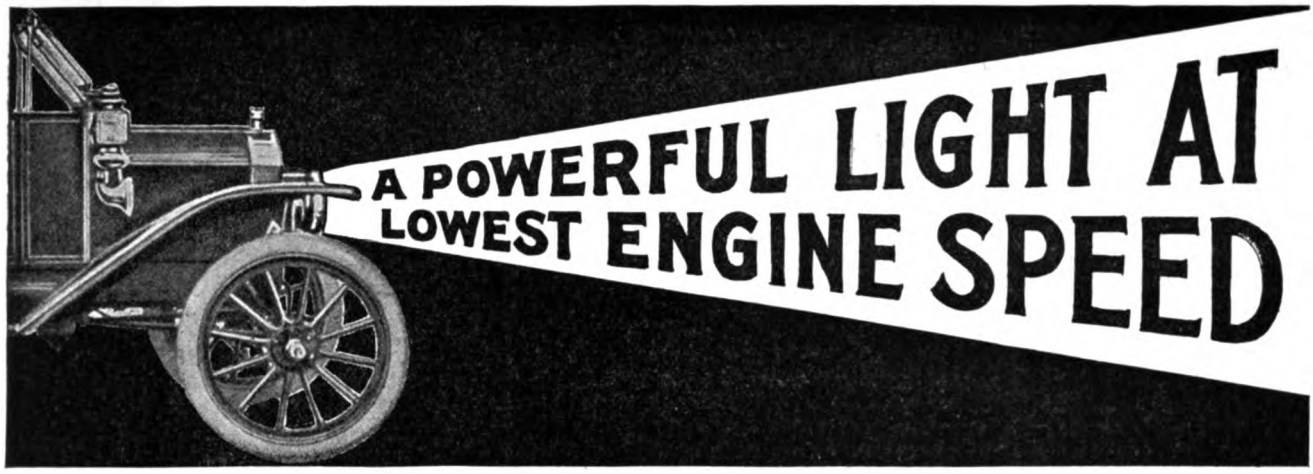
BEMUS BALL CONTACT TIMER

Every practical man who knows the Ford car recognizes the fact that this short stroke, high-speed engine requires a Timer capable of rapid, snappy action in the making of contacts and yet having durability sufficient for thousands of miles of running without loss of efficiency.

THE BEMUS IS BEST FOR THE FORD *BECAUSE*

CONTACT is made by a hardened tool-steel brush engaging steel balls with short, glancing impacts, both the brush and the balls turning each time so that fresh contact surfaces are continually engaged.

MOUNTING is direct on the time shaft by means of an extension piece. This brings each of the balls equi-distant from the brush. Result—absolute precision of timing.



STARTING is facilitated in cold weather because these contacts do not hold a body of oil to prevent passage of current.

DURABILITY of unlimited extent is due to a construction which eliminates all wear of the insulation. The roller brush is reversible, and when worn on both sides may be replaced by the user together with new contact balls at an expense of a few cents.

The New York Automatic Head Light Controller For Ford Cars

PRICE, $5.00

PATENT APPLIED FOR

Uses the regular Ford magneto, no batteries, charging devices, or complications. Every Ford owner will be vitally interested to learn that we have perfected a device that is applied by anyone in ten minutes, which will cause the regular electric light equipment on Ford cars (that have been installed by the owner or by the Ford Company) to deliver a powerful penetrating light at all speeds, *including the lowest speed at which a Ford car can be run.*

The Controller is *entirely automatic* in *operation* and at the same time wonderfully simple in construction. In addition to furnishing a strong light at all times, it prevents the burning out of the lamps at excessive engine speed. All the labor necessary is the removing and replacing of a single bolt together with the simple connecting of three wires.

No belts, gears, or moveable connections to the engine are employed.

It is the first and only solution to the electric head light problem on Ford cars. A trial of ten minutes will demonstrate its value. Orders filled in rotation received.

Our booklet tells a complete story. Gladly sent upon request.

Non-Skid Wrapped Tread

Mattson Unguaranteed Tires

Experienced Motorists in ever increasing numbers are turning toward

MATTSON
Unguaranteed Tires

They have discovered that they average better value—service and cost considered—than other kinds.

Nobody knows the life of a tire because nobody can foresee the conditions under which they will be used.

Under favorable conditions a tire will last longer—*guaranteed or unguaranteed*—than under unfavorable conditions.

MATTSON Unguaranteed Tire prices have decided thousands of motorists to try them. The Results MATTSON Tires give invariably decide them to keep on using them.

With increased and improved facilities—made necessary by the growing demand—we are entering upon our ninth year in the manufacture of unguaranteed tires.

While we sell only at wholesale we will be glad to tell you where you can get Unguaranteed Tires.

This information will be valuable, for you can save considerable in your tire expense by using MATTSON Unguaranteed Tires—Plain Wrapped or Non-Skid Treads.

Ask your dealer about the other famous MATTSON Rubber Accessories.

- ¶ High Grade Guaranteed red inner tubes.
- ¶ Reliners, Heavy, Medium, Light, Extra.
- ¶ Service tread boots — Lace-on — Hook-on.
- ¶ Blow-out patches.
- ¶ Repair Stocks for casings and tubes.
- ¶ Cementless patches.
- ¶ Hose connections for radiators, lamps, etc.

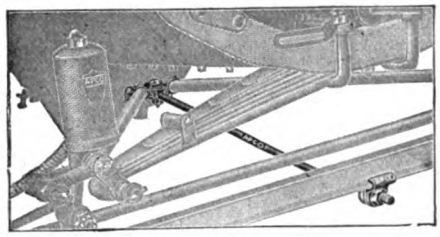
Five New TRADE APCO MARK Specialties

For Sale By All Live Jobbers and Dealers

REAR AXLE TRUSS

The Rear Axle on the 1915 Ford Car has been strengthened about 50% over any previous type, and this is not the first year that improvements have been made on this unit. To strengthen the old cars we offer the APCO Truss which is made from steel rods and semi-steel castings finished in black enamel. The rods are one-half inch in diameter and strong enough to give the axle the stiffness lacking in its original construction. The clamps go around the castings at the extreme end of axle housing, and do not put any strain on the pressed steel parts. The cradle that fits under the center of the housing is fitted with square sockets to accommodate the square heads that are made integral with rods. Bolts for clamps are square headed sunk flush in square sockets to prevent turning and to improve appearance. The whole outfit comes packed in a corrugated box 24" long and weighs 5½ pounds. If your axle housing leaks grease or your rear gears are noisy you need an APCO Truss to remedy the trouble. If not you need the Truss to prevent it. Installation is a matter of ten minutes with no tools but a wrench.

PRICE Complete $1.50



SPRING LEAF LUBRICATORS

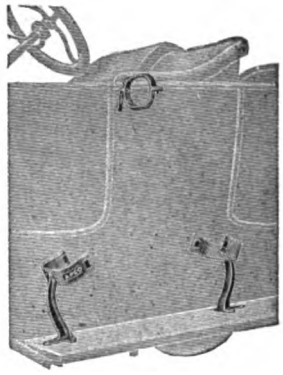
One concern selling an oiling or lubricating device for the leaves of automobile springs spent $20,000 advertising their product during last year. Another spring maker makes great claims for his springs because they are self-lubricating. There is no question about the advantages of having the spring well oiled. It's only a question of the means. The APCO Lubricator as shown in the cut consists of a pair of plates with oil reservoirs and felt inserts. These inserts soaked with oil rest against the sides of the spring leaves and give them constant lubrication which increases the riding qualities 100%. They are made from semi-steel, black enameled and are guaranteed to do the work as well as the highest priced article on the market. Set includes four pairs, two pairs for each spring. The only ones on the market that oil both sides of spring.

PRICE Complete $2.00

FRONT AXLE BRACE

The front radius rod on the Ford is made of tubing in which there is more or less spring or give. This give causes the bottom of the front axle to tip or bend back in going over rough roads, causing an unsteadiness in steering. The APCO brace consists of two ingenious clamps and a half-inch steel rod with a square head made integral. One of the clamps is attached to the extreme end of the front axle truss rod with three bolts, all having square heads to prevent turning, and the square head on the rod is held in this clamp. The other clamp is attached to the front axle and is held there by two nuts on the rod which go thru clamp. This device is one of the best accessories we have ever offered and is one that you need. Finished in black enamel. Can be put on the car with a wrench in five minutes. Packed in a corrugated box 23" long, weighs three pounds. There is no need of adding twenty pounds to the weight and five dollars to the cost of your car when ours will do the work. A new radius rod costs $3.00, you will never need a new one if your car is equipped with an APCO brace.

PRICE Complete $1.50

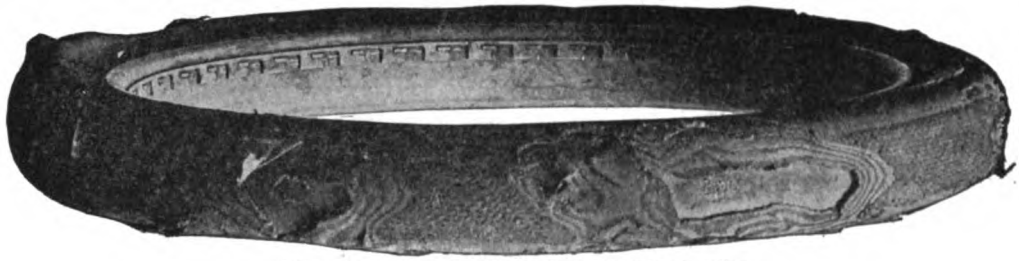


VALVE STEM PACKINGS

When the valve guides on an engine wear it is impossible to get a perfect mixture as air is drawn thru the space between the valve stems and the wall of the guides. This results in a skip that is impossible to find, especially at low engine speeds and full power cannot be obtained from the engine, as part of the suction stroke is wasted by drawing air by the valve stems. The APCO packing consists of a special steel stamping and felt washer which is held in position by valve spring as shown in cut. When in position the felt both prevents air from entering the cylinders and also lubricates the valve stem preventing further wear. They are necessary on the new cars as well as old, and the installation in either case is a matter of a very few minutes without tools of any kind.

Price per set of Eight 50c

SIDE TIRE HOLDERS



There are so many new rear tire holders on the market that the public is inclined to overlook the good points in favor of a side tire carrier. Absolutely the only advantage of having the tires on the back of the car is that of balance, and as a pair of shoes weighs but 20 lbs. this is purely an imaginary one. There are hundreds of reasons, however, why you should use APCO Side Tire Holders, and the following are a few, any one of which is sufficient for you to decide in their favor. 1. They keep the tires clean. 2. They keep the tires away from the hot exhaust. 3. The tires can be removed in five seconds and replaced in same time. 4. They can not be lost off the car. 5. They are much neater in appearance. 6. They can be installed in ten minutes. 7. With them it is possible to carry a trunk at the rear. 8. They make unnecessary the changing of tail light location. 9. They weigh seven pounds less than the lightest rear holder on the market. 10. There are no straps to lose or break. 11. Price is the lowest of any tire holder on the market, irrespective of advantages. 12. Special catch on top bracket locks automatically when closed and lock need not be used unless wanted. 13. Screws that hold bracket to body cannot be removed with tires in place. 14. Lock is solid brass mail type which opens automatically when key is turned. 15. Lock clasp is rubber covered to prevent rattle. Furnished in black enamel only. Packed in corrugated carton 6"x11"x7½" and weighs seven pounds. Complete with bolts, screws and lock. Will fit two 3½" tires or one 3" and one 3½".

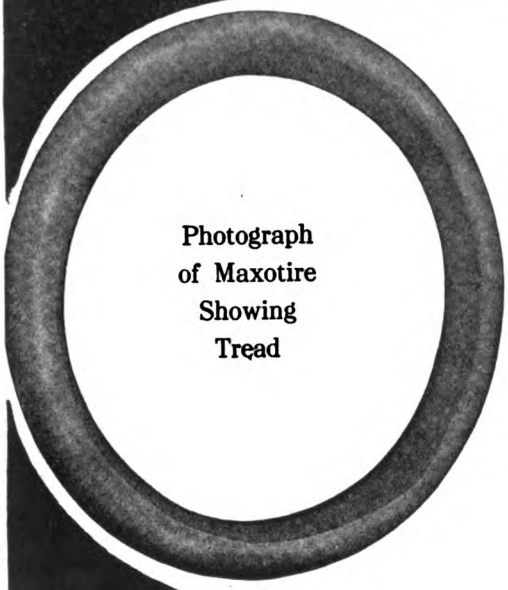
PRICE $2.00

AUTO PARTS CO. - Providence, R. I.

Please mention the Automobile Dealer and Repairer when writing to advertisers.

Digitized by Google

Your tires may often be worn down like this without danger of blowout or tire trouble.



You may now run your tires until there is little left of the outside shoe.

The secret of it all lies in the MAXOTIRE which is in reality a perfect tire having a rubber tread, fabric and bead. The MAXOTIRE is so scientifically constructed that it fits the inside of your tire perfectly. It leaves ample space for your inner tube and protects it from being damaged in any way.

The layer of very tough rubber covering the tread surface of the MAXOTIRE acts as a cushion between the MAXOTIRE and the outside shoe.

When the tire strikes a stone or is put to any great strain, this elastic rubber between the two fabric bodies of the tire and the MAXOTIRE equalizes the strain of both and prevents fabric breaks as well as blowouts.

·MAXOTIRES·

Photograph of Maxotire Showing Tread

Nothing like the MAXOTIRE has ever been sold before

Rubber-treaded MAXOTIRES make your tires practically puncture-proof. Tacks cannot reach the tube, while spikes or nails are invariably turned aside.

When MAXOTIRES are placed in tires this tough rubber tread comes in contact with the inner surface or fabric of the tire. This rubber tread clings to the tire like an overshoe to the sidewalk. There is, consequently, no friction; no heat generated; and no chance for the MAXOTIRE to slip and injure the inner tube.

Smaller inner tubes are not required for use with MAXOTIRES; however, they can be used with success at a saving to you of about 25% of their cost.

USE MAXOTIRES

HAVE TWO TIRES PROTECTING YOUR INNER TUBES

Take No Chances This Spring. Equip your tires with MAXOTIRES before taking your car out. While your car has been standing idle during the **winter,** your tires have deteriorated. They are in much worse condition than the outside appears. Tires blow out in nearly every case before the tread is hardly worn. This is due entirely to internal weakness which no one is able to discover.

MAXOTIRES will make your tires **trouble proof** during the coming season and enable you to get the full wear out of every tire. They are not an experiment but the result of seven years' experimenting by the people who invented the first reinforcements for automobile tires.

AUTO OWNERS: See your dealer, he may have MAXOTIRES in stock (for many have), however, if he hasn't—write for our complete free illustrated catalog and prices, express prepaid.

An Expert Opinion On Micro Piston Rings

"The writer personally tried out Micro Piston Rings and found that they are without question the best piston rings obtainable.

"These rings were put in cylinders that have been run from one to four years, without being reground or re-machined, which, in about 36 hours test, gave perfect compression. This I believe to be all you could ask of any ring."

C. A. HERVEY, General Superintendent,
SEAGER ENGINE WORKS, Lansing, Mich.

Coming from such an authority as Mr. Hervey, this should be convincing. If you too would "personally try out Micro Rings" you would become equally enthusiastic.

Users all root for Micro Rings because Micro Rings actually **do** what ordinary piston rings **cannot** do—that is assure **lastingly** perfect compression and the fullest degree of useful work from the explosive mixture.

The sealed openings in a Micro Ring (see picture), remain as tight when the ring gets old as while new, instead of gradually opening up and weakening the force of each explosion as with plain rings.

The compression is further protected with Micro Rings by equalized pressure and by three distinct contact surfaces all around the cylinder wall. Gasoline and lubricant are kept on the respective sides where each does the most good. In other words, every bit of power is made available in going up hills or pulling heavy loads, and absence of excess oil in the combustion chamber reduces carbonization, and the tendency toward overheating, leaking valves, and smoky exhaust.

Micro Rings positively will not break or take a permanent set in fitting. The flexibility which we obtain by individual casting from specially processed fine-grained gray iron permits safe removal and replacement of Micro Rings any number of times.

Micro Piston Rings
The watchdog of a motor's power.

Your judgment in selecting Micro Rings will be more than vindicated on the first installation and you can make the trial at our risk. Business fairness, extensive manufacturing and rigid inspection to micrometer accuracy put backbone into our guarantee.

If your jobber cannot supply Micro Rings don't accept a substitute and be disappointed. Write us direct.

Your Old Car Is Worth Ten New Ones

if you only *know how* to cash in its possibilities in Family benefit.

With your permission we propose to *show you* thru the coupon below:

To many Automobile owners it may sound strange when we state so emphatically that Automobile Tours with parties of men, women and children (of any age), over any desired distance, may be made with far greater Safety, Comfort and Pleasure than is possible when traveling in Pullman parlor trains, but we do mean it and will prove it.

Have a Family Picnic Every Touring Day.

The desirable advantage of exclusiveness, independence and unexcelled sight-seeing possibilities while traveling by Automobile, saying nothing of reaching the far out-of-way places so entirely impossible to the railroad traveler, are the points of advantage universally admitted by everyone and need no mention here.

The detail that is not so generally known, however, is: How to equip a car to eliminate excess baggage and useless expense but still maintain every comfort and pleasure of the boulevard spin for each and all the passengers throughout the entire tour. Many car owners who have had reverse experiences, or, say road disappointments, may be a little skeptical because they failed, but we want every reader to be absolutely assured that all past failures have not been without real reasons.

Our experts are past masters in Touring, and after crossing and re-crossing the continent many times, touring and camping with their wives and children, their experience has eliminated many common errors, and like almost everything else in this life, there is a right and wrong way to start. In Automobile touring the right way happens to be much the easiest and far less expensive. We will be only too glad to help all interested Automobile owners for whom a special number of the SERVICE NEWS will be issued June 1, 1915, and copies promptly mailed to all applicants sending in the coupon request.

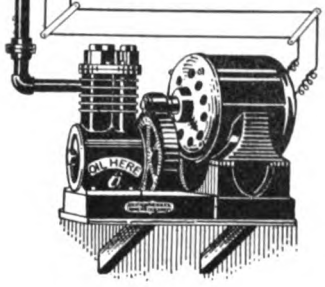
BRUNNER AUTOMATIC AIR SUPPLY



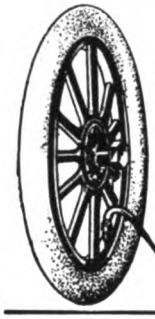
BRUNNER

THIS DOES THE TRICK

115 TO 140 LBS. ALL THE TIME

AUTOMATICALLY CONTROLLED

"Always on the Job"



A BRUNNER AUTOMATIC AIR COMPRESSOR OUTFIT WOULD IMPROVE YOUR SERVICE JUST ABOUT 100%

A **Brunner Automatic** would save you time and operating expense—and **eliminate your air compressor troubles**—because it is a practically constructed, mechanically perfect equipment that has proven by many years of satisfying service to be the "best ever." Any garage man who has one, or any jobber who has ever sold one, will tell you this.

The Brunner Automatic Controller Never Lays Down

because it is a large husky, correctly designed and well constructed instrument built to "stand up" and give you **Brunner Service,** and to you **Brunner Service means** the **best possible service**—if you have ever had your troubles with a cheaply constructed unreliable automatic controller you can appreciate what it would mean to you to have a Brunner Automatic in your garage, it would mean—less worry—less expense, and it would mean more trade and better trade.

It Will Pay You To Investigate The Brunner Line

You might not need a Brunner Air Compressor Outfit right now—but you may need one any minute, and a No. 12 Brunner Catalogue with the name of the Brunner Jobber near your town would be a handy thing to have about the place—because we always carry a large complete stock in our warehouse ready for shipment and a telegram from a Brunner Jobber will start one your way instantly.

PLEASE BEAR IN MIND:—Our plant has been devoted to the **exclusive manufacture** of **Garage Air Compressor Equipment** for many years and there are over 17,000 Brunner Air Compressor Outfits in successful operation—it is not a troublesome side line proposition with us—it's a serious business—and we understand it.

Write for Catalog showing our full line and the name of the Brunner Jobber who covers your territory.

BRUNNER MANUFACTURING COMPANY - - UTICA, N. Y.

For the thorough overhauling at the garage, for the sudden emergencies which arise on the road, or for the week-end tinkering by the car owner, there is no one tool that will do as much as the

Starrett Ratchet Wrench

BY INVITATION MEMBER OF

NEW YORK U.S.A.

It will turn any standard nut or bolt in all sorts of difficult places;—places where the ordinary monkey wrench is useless. The ratchet permits rapid action with only a short arc swing. The extension reaches into otherwise inaccessible places. The drilling attachment furnished with the wrench takes any square shank twist drill from ⅛ to ½ inch. A reversible screwdriver makes it handy for turning screws of various sizes.

The L. S. Starrett Co.,
World's Greatest Toolmakers
Athol - Mass.

This complete outfit sells for only $15.00. You'll find it a valuable outfit if you have a garage, and you can make profitable sales on it as a dealer. Write to us now for information, prices and catalog No. 20 D.C.

No Danger—If the Brakes Hold!

You who sell brake lining will multiply your sales and at the same time do the right thing by your customers, if you will make the following two suggestions your rules:

1. Test the brakes and brake lining on every car that comes into your hands. Not a slow-stop, but a real test—an emergency test.
2. Sell Thermoid because it is 100%—first to last—because Thermoid can be trusted with LIVES.

Thermoid
HYDRAULIC COMPRESSED
Brake Lining-100%

Thermoid is honest brake lining all through. There's the same gripping friction at the core as on the outside. It is forced by hydraulic compression into a substance of uniform density, and, though worn paper-thin, it still grips and holds instead of being loose and stringy inside with just a thin friction surface, like the ordinary, loosely-woven brake lining.

Watch the brake lining—guard safety with 100% Thermoid

Cannot be burned out nor affected by oil, heat, water, gasoline, dirt.

THERMOID RUBBER COMPANY

TRENTON, N. J.

Our Guarantee: Thermoid will make good, or we will.

Carbon removed

for

5c. to 12c. per cylinder

And as *thoroughly* as the best job you ever saw! Simplicity itself. Takes fifteen minutes. Absolutely harmless to everything except carbon, which it abolishes.

Real Authorities

use and endorse it

Besides this endorsement we have the strongest kind of letters; from the Sales-Managers of well-known Auto Manufacturers—from auto Engineers, Superintendents, Public Officials and hundreds of other enthusiastic users.

Mr. GLENN CURTIS

"A single application will loosen and remove the carbon, clean the plugs and... increase the power and efficiency send me ten cans."

GUARANTEED OPCO OIL PRODUCTS **CARBON REMOVER** GUARANTEED OPCO OIL PRODUCTS

has real MERIT—it is PRICED RIGHT. One of the best repeaters known—a very small number of dealers sold over 15,000 cans in 9 months.

DEALERS OWNERS

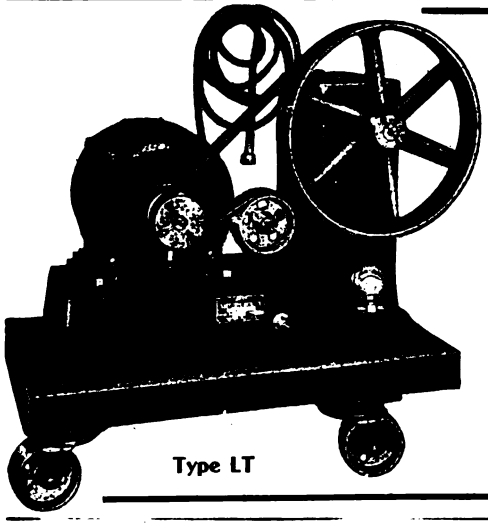
The art of profit making

One criterion only can be used in measuring the success of any business. How much ***net*** profit has been made, is the acid test for the retailer as well as the manufacturer to use. Unless there is something left out of the proceeds of the business after the cost of doing business (which includes the interest on your money and wages of management) has been deducted there is something wrong.

Maybe your margin of profit is too low. Maybe the manufacturer has charged you up with wasteful general advertising. No excessive advertising charges are figured in on the cost of the Samson-Tiger hand horn. It is offered to the dealer at a fair list (**$5.00**) with a profit-making discount. Write today for dealers' discount and sample horn at our expense.

The Samson-Tiger Hand Horn



is the only shaft-driven horn on the market. It is not a "push type" horn with a plunger or lever to stick, but is always ready to operate. It has a one-piece brass projector; it is beautifully finished in black with brass or nickel trim, and the tone volume is unequalled in any other hand horn produced.

Note: "Dealer helps" is the kind of advertising you want, and the kind of advertising we believe in. To our dealers we supply effective literature and beautiful counter display signs merely for the asking.

AMERICAN ELECTRIC COMPANY STATE AND 64th STS. CHICAGO

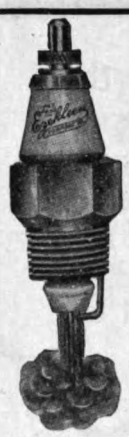
1/3 Of Your GASOLINE SAVED BY THE

Economy Gasoline Improver

OR SUPER-CARBURETOR

Cold water will not give off steam, and the best carburetor on earth will not give off real vapor without the assistance of heat, at any time of the year. **Boiling Gasoline** is used at the big races in the middle of the summer.

The Economy Gasoline Improver uses waste heat from the surface of the exhaust pipe to heat the gasoline in the gasoline pipe before it enters the carburetor, greatly increasing the power, improving the running of the engine, decreasing the deposit of carbon and permitting a saving of **One-Third of Your Gasoline. YOU CAN SEE IT SAVE.**



We guarantee that with the **Economy Gasoline Improver** on your car you can turn off the flow of gasoline to the carburetor ⅓ after the engine is warmed up, and still get full efficiency.

PRICE $2.35 **A Special Offer will be made once to each new dealer. Write for it.**

Order through your dealer or direct from us. We ship by insured mail same day order is received. **We pay the postage.**

"EZEKLEEN"

THE ONLY SPARK PLUGS MADE

THAT DO NOT DEPEND UPON THE ELECTRIC SPARK TO IGNITE THE GAS

The EZEKLEEN and Mfrs. SPECIAL SPARK PLUGS have a projecting hollow insulator that is molded in the shell. There is no bushing nut holding the insulator against the shell; therefore, there is no pressure on the insulator to hold the insulator against the metallic compression-tight joint. This projecting hollow insulator is in the flame at each explosion and becomes very hot. Oil or carbon will not stay on this red hot insulator. At each compression stroke of the motor, this hollow insulator is filled with gas. This column of gas becomes very highly superheated and does not need a high voltage spark to explode it. The gas in the cylinder is ignited by the explosion from this superheated mixture that is inside the insulator that is ignited by the electric spark. Therefore, this spark plug does not depend on the electric spark to ignite the gas in the cylinder.

They cannot be short circuited in a Ford car. They are just the thing for a scored cylinder that has poor compression and that rapidly fouls the old time spark plug. They will improve the ignition of any motor that is now equipped with the old time spark plugs.

On sale in all first-class garages. If your dealer does not have them, write for our free trial proposition. You are under no obligations to buy. We have an interesting proposition for a distributing company that can handle a large territory.

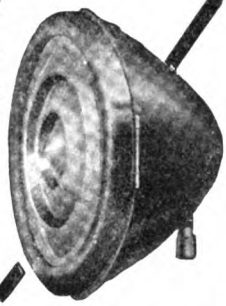
The New Appliance For Headlights

KLEARGLOW is the latest and most improved device for its purpose. Originated in Switzerland—popular throughout Europe. Made entirely of scientifically designed, corrugated glass surfaces. Takes away the glare that causes so many motor car accidents—so many smashed cars—yet does not absorb any of the power furnished by the lamps, as with dimmers and similar devices. KLEARGLOW casts *all* the light *all* the time. "Dimmers" are dangerous—KLEARGLOW is safe. KLEARGLOW does not have to be removed when making country trips, in order to obtain enough light.

KLEARGLOW
The Auto Light Diffuser



gives all the *safe light without the dangerous glare.* Lamps equipped with KLEARGLOW conform to the varying laws of different localities covering automobile headlights. KLEARGLOW prevents the arrest and fine of owner or chauffeur, saving much expense, loss of time and unnecessary annoyance.

You ought to put KLEARGLOW on your car *now.* Fits any car and goes in place of present headlight glass. Will make your car look better. The moderate price—$3.75 per set—is really an investment—for it is proof against injury to person and damage to car as well as police interference due to common headlights.

Our interesting illustrated folder points the way to better and safer motor trips. Tells about our fifteen-day trial offer—we make KLEARGLOW "prove up" *before* you buy. Just drop a post card for the folder TODAY. Address

AUTO TIRE VULCANIZING CO., Lowell, Mass.

The New Schrader Quick-Acting Dust-Cap

The operation of testing the air-pressure in tires having been found on occasion difficult and irksome by reason of the jamming together of the valve stem and dust cap, the firm of A. SCHRADER'S SON, Inc., have designed and placed on the market a new "Quick-Acting" Dust Cap which can be removed from the valve stem by a simple quarter turn.

The new SCHRADER "Quick-Acting" Dust Cap eliminates the work of screwing the cap down the entire length of the valve stem to the felloe of the wheel. All that is necessary is to slip the cap over the valve and turn it one-quarter turn. This locks it securely to the valve stem. To unlock, simply give one-quarter turn in the opposite direction

VOL. XIX, No. 3. NEW YORK, MAY, 1915. PRICE { 10c PER COPY / $1.00 PER YEAR

AUTOMOBILE LUBRICATION.

Conclusion of the Subject with Some Reference to Carbon, Graphite and Acidity.

BY SYDNEY F. WALKER, M. E.

The reason for the tendency to gum has been explained in a previous portion of the article. Mineral oils have no tendency whatever in that direction, and only certain of the vegetable oils. Any tendency to gumminess that would arise, therefore, would be due to an undue proportion of one of the gummy oils in the lubricant. The gumminess referred to has a double effect. It not only causes a deposit of its own, but it also forms a bed for carbon to deposit, so that the evil arising from the deposit of carbon is very much increased.

It is somewhat difficult to give a test that will be satisfactory of the tendency to gumminess. Probably the best test that could be arranged would be to paint a piece of canvas with the oil under examination, and to expose it to a draught of air. The canvas should be suspended in a position where it is exposed to air, plenty of it, but not to the sun's rays; and a measured quantity of the oil to be tested should be employed to paint the square yard of canvas, and it should be left to dry, provision being made of course for the oil to drain off. There should be a certain standard time also for the drying and allowance should be made for the time of the year. In hot, dry weather the drying will take place more quickly than in warm, muggy weather. In cold weather, if there is a sharp breeze blowing, the drying may also be fairly quick. Practical experience will dictate, as in the other cases, how the best arrangements can be made. Probably it will take something like a week to obtain a proper test; though under certain conditions it may take considerably less. In any case, practical experience with different oils will be the best guide. As a preliminary, a number of smaller pieces of the same kind of cloth might be taken, hung in a line where they would all be exposed to the same atmospheric conditions, and all painted with different kinds of oils. One of them should be painted with good linseed oil and careful observation taken upon the time required for it to dry, as a standard for comparison with the others.

The Question of Acidity.

The presence of acid in any lubricating oil is of as great importance as any of the other points that have been mentioned. As will be remembered, the acid can either be present in the original oil, in the case of impure sources; or as is more probable, it can be left in the oil after purification with sulphuric acid. Fortunately there is a very simple test for acidity. Paper soaked in a solution extracted from certain lichens called litmus is made in rolls so that a small piece can be torn off and dipped in any liquid that is suspected of containing acid, and it is also made in sheets, so that a drop of the liquid can be allowed to fall on the sheet. It is sold at a very cheap rate. The litmus paper changes color. If it is blue it changes to red if acid is present. It is also a test for alkalis. For that purpose it is made red and when it is used to test a liquid, if any alkali is present, it changes color to blue.

The Deposit of Carbon.

The matter of the deposit of carbon is also made a great deal of by vendors of lubricants. In the writer's view, however, in the case of automobile engines, it is not of great importance, so far as the lubricant is concerned. The quantity of carbon that is likely to be deposited from the lubricant is very small compared with that which is constantly deposited from the gasoline itself, unless the lubricant supplied to the cylinder is very much in excess of the requirements, and the surplus is burnt. Those who are familiar with the oils and fats used for illuminating purposes will remember that vegetable oils and fats will burn with a wick in the open. On

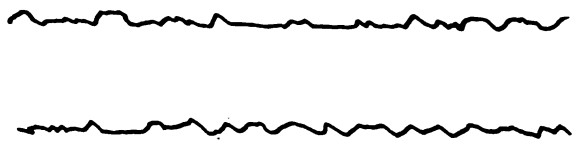

Fig. 26—Diagrammatic sketch showing how machined metal surfaces appear under the microscope.

the other hand, mineral oils, if burnt in the open, smoke so badly that practically no light is given, and the reason is that they require a certain quantity of oxygen for their complete combustion, a larger quantity of oxygen than is apparently necessary with vegetable or animal oils. It is this tendency to smoke, which is the reason for the deposit of carbon from the gasoline charge in the cylinder of the motor car engine. Every user of a motor car knows what a nuisance the deposit of carbon is; and there are numerous apparatus upon the market, and various chemicals designed to clear out the carbon after it has reached a certain thickness. The presence of the carbon in the cylinder is due to imperfect combustion, just as the smokiness of the flame of a mineral oil lamp is. The charge of gasoline is not completely burnt, and consequently a small proportion of carbon is left after each explosion, and the thickness builds up. It builds up very much more quickly if there is some bed for it to deposit on, such as would be produced by a gummy lubricant; but in the writer's view, the quantity of carbon deposited by any lubricant that is likely to be employed in motor car engines, would be very small to that deposited by the gasoline charge itself, except in the case mentioned above, where there is an excess.

The Use Of Graphite.

As readers of the Automobile Dealer and Repairer know, the use of graphite has been advocated

Digitized by Google

very largely, and particularly by one firm who have made a specialty in its preparation, for the lubrication of motor car engines. It is sometimes advocated for use alone, but more frequently, as an addition to the ordinary lubricant.

The argument upon which the use of graphite is based is a very important one, and it necessitates the question of lubrication being looked at from an apparently different point of view to that that has been used above. Advocates of graphite say, and with justice, that however carefully two surfaces that are to slide over each other are machined, if they are examined under the microscope, it will be found that there are small holes and small pin points all over both surfaces and that these holes and pin points tend to engage with each other, when the surfaces are sliding over each other. There is no doubt that there is a great deal in this. Fig. 26 is an endeavor to show diagrammatically the appearance of surfaces as they would look under the microscope. Every one who has handled machinery is acquainted with the fact that shafts, for instance, which run in bearings run much more easily and sweetly after they have bedded themselves.

There is a piece of apparatus very much used in fitting shops, for cleaning up, known as file card; it is used very largely in the textile industries for breaking up the fibres, ready to be straightened

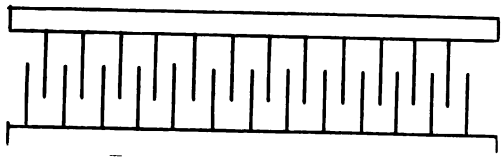

Fig. 27—Diagram showing the arrangement of two pieces of file card, with their teeth interlocked.

out and to be formed into a continuous length. A piece of card consists of a piece of canvas, or any convenient substance as a holder, with a number of small pieces of steel embedded in its surface. It makes an excellent tool for cleaning off hard dirt from any piece of apparatus. If we imagine that two of those pieces of card are placed against each other with their points directed inwards, as shown in an exaggerated form in Fig. 27, and are caused to slide over each other; we have some idea of what is supposed to take place when two machine surfaces slide over it. The points on one card are supposed to fit into the spaces between the points on the other card, so that the cards lock together, and require a considerable expenditure of energy to separate them, and to cause the two cards to slide over each other. Similarly, the two machined metal surfaces which hold these minute pin points and holes, are believed to lock together in the same manner as the cards, and to give rise to friction.

The advocates of graphite claim, and it appears to the writer with considerable justice, that by the use of graphite the pin points are masked, and the holes are filled up. It is as though the two pieces of card referred to above were filled up right to the top of the steel points with some substance that would stand the pressure between the two when they are made to slide over each other; and will present two smooth surfaces, in place of the pin points and spaces between the pin points shown in Fig. 26.

As the writer understands the matter, where an oil of a certain body, a certain viscosity and a certain specific gravity has hitherto been employed for the lubrication say of a motor car engine by the addition of a small percentage of flake graphite, ground up to a very fine powder, a much lighter oil, one of very much lower viscosity, and usually lower specific gravity, may be employed. The graphite will not be dissolved in the oil; but will be carried in suspension, though practically imperceptible, except that the coloring of the oil will naturally be darkened. When the lubricant is in use, when the engine is running, the graphite is carried with the oil to the bearings of the crank shaft and to the piston and gudgeon pin, and the lighter oil evaporating due to the heat to which it is subject, the minute particles of graphite are deposited in the holes, and between the pin points mentioned above, and gradually form a sort of skin of plating over all the surfaces that are sliding over each other. A graphite surface is in itself smooth, it possesses a considerable amount of the "oiliness" that is so necessary for a lubricant. Surfaces upon which a graphite has been deposited, slide over each other with comparative freedom, and it follows that a very much thinner skin of the liquid lubricant, of the oil itself is required between the two plated surfaces. Perhaps a better illustration of the action that takes place between two machined surfaces would be, that of two smooth cut files rubbed against each other, or arranged to slide over each other, as shown in Fig. 28.

To Sum Up.

And now to sum up. The problem involved in the lubrication of a motor car is a very wide one. The most important part is, of course, the lubrication of the main bearings of the engine, of the gudgeon pin and of the piston. For this purpose, the above analysis would appear to show, that a comparatively thin mineral oil will be best, to which has been added a small percentage of one of the non-drying vegetable oils, or a small percentage of one of the animal oils, and also a small percentage of pure finely divided graphite. There is a point, however, that has to be remembered; the lubricant must not be too thin. The viscosity of mineral oils increases almost in the same proportion as the flash point and ignition point. It is of the greatest importance that an oil of too low a flash point shall not be employed in the crank chamber, or in fact anywhere, because it will be subject to somewhat rapid decrease in quantity by reason of evaporation. As explained above, the really important matter in connection with the flash point is the temperature at which vapor comes away from the oil, and it may be taken that all vapor which comes away from it is waste. It may be burnt; but as has very properly been remarked, the office of lubricating oil is not to burn, but to lubricate. It would appear therefore that the flash point of any oil employed in the crank chamber should not be less than 300°F. With regard to its viscosity, the flash point will probably govern the viscosity; but this is one of the things that must be discovered by actual practical experience, and almost every engine will vary in this matter from every other engine. It will be evident that with the type of engine in which the crank chamber reaches a fairly high temperature, the viscosity of the lubricant at

Digitized by Google

ordinary temperatures must be higher than with engines in which the design has enabled the crank chamber to be kept at a lower temperature. In all these cases, there is nothing like practical experience. Run an engine under actual working conditions with different kinds of oil, and choose that which answers best under all conditions of service and keep to that oil; but see that you get the same oil by means of the test described above. But though the crank chamber lubrication is the most important, it need hardly be mentioned that it is by no means the whole of the lubrication. Every motor car is, so to speak, full of surfaces sliding over each other all of which require lubrication. There is the half time shaft; there is the clutch rod; there is the cardan shaft where one is employed; there are the axles of the wheels of the vehicle itself; there are the axles of the gear wheels; there are the teeth of the gear wheels; there are the teeth of the sprocket wheel where chains are employed, and so on. Nearly all that has been said above applies, however, to pretty well every pair of surfaces that are sliding over each other, except that they are not subject to the high temperatures to which the lubricant inside the cylinder is. Some of the parts that require lubrication, the valve rods for instance, and some of the moving parts that are in close contact with the engine are subject to a moderately high temperature. With most of them, however, a mineral oil of not too high a viscosity, not too high a flash point, mixed with a small quantity of one of the non-drying vegetable oils or a small quantity of one of the animal oils; and also mixed with a small quantity of pure, finely divided graphite, should answer satisfactorily. Probably one kind of oil will answer for all the bearings that have to be lubricated; so that the oil can be prepared in fairly large quantities at the works, or can be kept ready at any garage.

The question of the delivery of the lubricant to the different bearings is again a most important matter, and there is a great deal to be said for forced lubrication as against gravity, with or without one of the sight feed apparatus. The high speed steam engine that is now so very largely employed in the United Kingdom and in other parts of the world for driving electric generators was not successful as a double acting engine until forced lubrication was introduced. The high speed reciprocating steam engine is being superseded by the steam turbine; but that apparatus also depends very largely for its success upon forced lubrication.

There is one serious objection to the use of forced lubrication in motor car work; viz., the pump and its accessories are something additional to be looked after. Forced lubrication requires not only the pump, but pipes leading from it to every bearing that is to be lubricated, and it also requires pipes leading from the bearings to the reservoir from which the pump takes its supply. It may fairly perhaps be claimed that what has been done with the high speed reciprocating steam engine can be done with the gasoline engine; but it should be remembered, that while the high speed reciprocating engine runs at a maximum of 600 revolutions per minute, the gasoline engine runs now at 2000 revolutions, and will probably be running at 3000 before long. The advantage of high speed in lessening the weight of the engine is so great that in all probability speeds will go on increasing up to the limit. There will be a limit of course to the advantage of increased speeds.

The methed of forced lubrication also has the great advantage, that the oil from the crank chamber can be employed, the crank chamber being a reservoir, and all the drain pipes from the different bearings can be returned to the crank chamber. The crank chamber is the natural reservoir, the natural receiver of the oil from all parts, except such parts as the gear wheels, the differential, etc., which requires special treatment.

With regard to the change gear wheels, the differential, etc., as the writer understands the matter, a thicker, a more viscous lubricant can advantageously be adopted. The conditions in the gear case and in the differential, etc., are quite different from those where shafts are running in bearings. It is of the very highest importance that the gear wheels

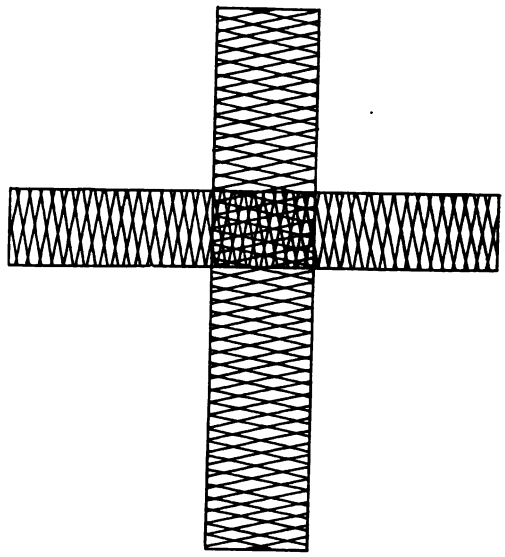

Fig. 28—Diagrammatic sketch showing two smooth cut files rubbing over. each other.

that are sliding over each other should be well lubricated; that there should be a good skin of the lubricant between the teeth that would otherwise be in contact; but under the conditions ruling, a certain amount of heat will almost necessarily be liberated, and that will tend to keep a comparatively viscous lubricant in the fluid state, at any rate, in a sufficiently fluid condition not to set up resistance to the passage of the teeth over each other. Again, however, the substance that could be employed for the purpose would appear to be a comparatively viscous mineral oil, with a comparatively large quantity of one of the animal fats and with a fairly large percentage of pure, finely divided graphite.

There is one point which the writer has not referred to; viz., the possibility of a lubricant setting, becoming more vicid, tending more to the nature of a fat than an oil in cold weather. It does not appear to him that this is a very serious matter except in the case of possibly the gear wheels and the differential. Immediately the engine is running, there is sufficient heat liberated, even in the coldest weather to undo any solidifying that a low temperature may have introduced.

THE SCIENCE OF STARTING.

The Effect of Starting and Turning—Things the Driver May Do to Save Tires.

BY JAMES F. HOBART, M. E.

The other day I watched a driver start a car at the public market in Indianapolis, Ind., and the manner in which he got under way was good—for the tire manufacturer but for nobody else. The car was standing square against the curb—they park cars here in that manner where curb space is scarce and streets wide—and the driver evidently being in a hurry, he threw the steering wheel clear over as far as it would go—"hard aport," an old sailor would say—then he threw in the clutch so suddenly that the car gave a jerk, the front wheels skidded a short distance, then the car spun around and went off on a tangent so fast that the driver had all he could do to bring the wheel back quickly enough into the straight ahead position.

Evidently this driver had no idea of the severe work placed upon the tires by such a start. Probably he never gave the matter a thought or even knew that it made any difference in tire wear, as to at what angle a sudden turn was made on a start. But it does make a whole lot of difference in tire wear, in the angle at which a quick turn is made as the following diagrams will show.

In fact, were it not for the saving effect of inertia, the driver who makes quick start turns would probably tear tires to pieces faster than he could afford new ones. It requires a certain time for the force of an engine to be transmitted to the wheels and during this time the clutch must slip and that alone, saves many a tire.

When making an ordinary turn, the wheel is thrown over or around until the front wheels of the vehicle stand at about 20 degrees with the rear wheels. Even when the wheel is thrown around very quickly, there is little effect upon the forward tires for the reason that the angle and turn is so slight. But when that driver started his car from

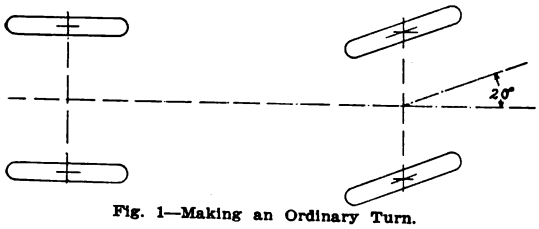

Fig. 1—Making an Ordinary Turn.

the market, the other day, he threw the wheel over about 60 degrees as shown by Fig. 2. It might have not been quite 60 degrees, for I had no way of measuring the exact angle, but anyway he went the limit and threw the wheel over as far as it would go and the wheels stood about as shown by Fig. 2.

The start was so fierce that a basket of provisions upon the seat by the driver, was overturned and its contents sent rolling upon the seat, nearly every article falling to the floor of the car, which indicated that the movement of the car was nearly all sidewise and very little in a forward direction, in which case the articles would have stayed upon the seat.

The driver of that car—and other drivers too—might very profitably do a little figuring as below set forth and then they would go a whole lot easier on making sudden turns. There is a way of finding the power expended, or the stress set up in the tires while making a sudden stop, and this way is without any tedious calculating whatever. Figs. 3 and 4 show this method and how it is worked. In Fig. 3, the line AB indicates the direction in which the automobile was headed when it was started up and the line AC, 20 degrees away, shows the new direction. Now we have to find out how much the engine will push in order to work out this problem and we will assume that its power will push the car ahead at 150 pounds. It may be more or less, but we will assume that it is 150 pounds and use that amount in our calculations.

To make the diagram shown by Fig. 3, which rep-

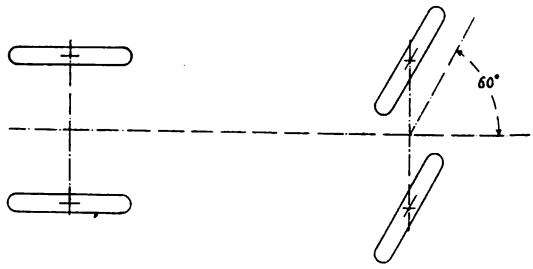

Fig. 2—Making a Short Turn.

resents the stress of making a long or 20 degree curve and as stated, the line AB represents the pull of 150 pounds and to lay down this line, take any convenient scale, say three inches to the 100 pounds, or 6 inches, or 2 inches, as may be convenient. In this case, the line was drawn at a scale of 100 pounds per inch. The engraver probably has changed the scale in making the drawing so you had better make a drawing of your own and not try to work with the small scale used in the illustrations.

Draw the line AB equal to 150 pounds by the scale used. As 100 pounds per inch was used in making the drawing from which Fig. 3 was used, line AB is made 1½ inches long. Then draw line C at the angle of 20 degrees, laying off the angle with a protractor or scale of chords as you may have either at hand. Next, draw the dotted line BC, from B, making this line exactly square (perpendicular to) line AC. Next, measure the length of line BC by the same scale used in laying down line AB. Measurements in this case, show that line BC is (on the original drawing) about 5.1-100 inch in length, hence it will represent a stress of just about 51 pounds. Not pounds per square inch, but 20 pounds without any other qualifying words.

As the line AB equals 150 pounds, and represents the force which drives the car ahead, so 5.1 pounds represents, through line BC, the side force upon the car at the instant of making the turn. Also, the line AC, represents the power applied to the car to send it on its new route. This may be measured, and you can calculate it also, to serve as a check upon your graphic method of determining the length of line BC. Measurement of line AC shows it to be about 1.41 inch in length, therefore the power given to the car on its new course is 141 pounds. Right in Fig. 3, there comes up a good question for you to discuss with your brother drivers. This question is: How, when only 150 pounds was the push applied to the car, can there be 141 pounds applied in the direction? But while you are discussing the

Digitized by Google

matter, bear in mind that while 150 pounds push is applied to the car, 141 pounds is used in the useful work of sending the car in its new direction and 51 pounds is expended in trying to skid the car sidewise, a stress which has to be resisted by the grip of the wheels upon the ground, consequently the tires have to stand this side stress in addition to the 150 pounds of straightaway pull in the direction of the wheel rims.

When the short quick turn is being made, the side stress is as shown by Fig. 4. The line which was AB, is now DE. Line AC is replaced by line DF which runs off at 60 degrees. Measuring this line shows that it is about ¾ inch long, which it should be, as in an angle of 60 degrees, the shorter leg is always half the hypothenuse. This means that 75 pounds, or one-half the applied power, is used to push the car in its new direction DF, while the line EF measures about 1.3 inch in length and therefore stands good for 130 pounds of side push upon the tires of the car. Almost as much as the entire push applied by the engine—another very interesting question for discussion, the matter of whence comes this amount of applied stress? Some 205 pounds, according to the diagram, Fig. 4.

If you wish to prove that this amount of stress is really developed, you may do so very readily and all the apparatus needed will be three spring balances such as are used by ragmen, icemen and some other traders. If the spring balances you can get hold of will not weigh as high as 150 pounds, then take some part of that weight, within the capacity of the instruments. You can make the test as well with 15 pounds as with 150 pounds, in which case the other weights would be 5.1 and 14 pounds respectively. A tin can with sand in it will answer for the weight of 15 pounds.

Some cord or stout string will be needed and a couple of nails which are to be driven into a convenient wall or attached to some beam as shown by Fig. 3, and attach the strings as shown from I and J, to H. Two of the spring balances are hooked over the nails as shown at K and L, and the strings are tied to the hooks of the balances and made long enough to reach to H, in such a manner that each

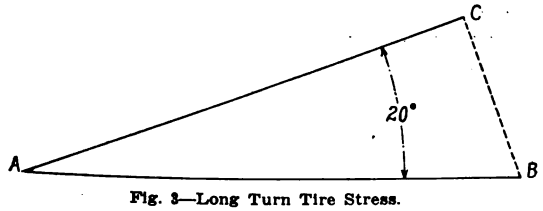

Fig. 3—Long Turn Tire Stress.

cord makes an angle of 30 degrees with a vertical line through GH. We may draw the angles directly upon the wall and then make the strings hang just right to exactly cover the marks. Next, measure off vertically from H, where the strings come together, a distance of 15 inches to represent the 15 in the other diagrams. Then, if we measure off 13 from H, on either cord, to I and J respectively, then we have an exact representation of the conditions shown by Fig. 4, with the exception that the figure is made double in order that it may be self-supporting. If we now draw the dotted lines JG and IG, we have the exact representation of two diagrams like that shown by Fig. 4, and joined along the 150 pound line.

The above being the case, we should, by hanging 150 or 15 pounds upon scale H, find a stress of 130, or 13 pounds upon each of the scales K and L. And this will be found so, provided the cords are made of the right length to bring them exactly over the 30 degree lines drawn upon the wall. Should the cords be lengthened, the load upon the scales—the upper ones—will be lessened and if the cords are shortened, the load upon each of those scales will be increased, until the point is reached where the cords HI and HJ form an angle of 120 degrees with each other, or each is 60 degrees from the central vertical line, then each scale will show 150 or 15 pounds and the little dinky 15-lb. weight below H, Fig. 5, is re-

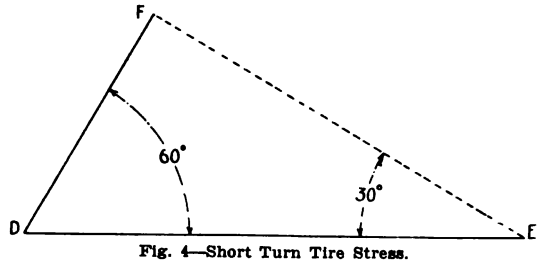

Fig. 4—Short Turn Tire Stress.

sponsible for a showing of 30 pounds upon the scales below K and L. Can you tell from whence comes the extra showing of weight?

From the above, it will be seen that the matter of 150 pounds push ahead in an automobile, is not in error when it is claimed to give 141 pounds push in the new 20-degree direction and 51 pounds more pressure crosswise the wheel and tire. The same shows true in the 60-degree test, both with the automobile wheel diagram and with the scale and string test.

Furthermore: The more the strings are flattened, or moved to a flatter angle, the stress will be increased in the two upper scales and remain the same in the lower one. And this may be carried out indefinitely until the cords have been flattened out almost straight, the strain upon the scales showing more and more, with no limit in sight. And, there is none; for, were it possible to keep the cords perfectly straight, without their sagging in the least, they would pull against each other with an infinite force. There would be no limit to it, and one pound hung upon a perfectly straight line, would pull enough, provided the line stayed straight, to pull the world one side instantly!

But, unluckily—or perhaps luckily—there is no known way of keeping such a line perfectly straight. We have no material in engineering strong enough to stand the stress. Even a 24-inch steel I-beam, placed across a ten foot space, will sag enough to be measured with delicate instruments. And were we to make a frame of stout steel and put a bolt through it and screw up the nut with the bolt in a horizontal position, we could not screw up the nut tight enough but what the bolt would sag a trifle under its own weight. It would be very, very little indeed, but it would settle all the same unless the bolt were strong enough that we could screw it up with infinite force —with all the force in the world and everywhere else.

To come back to our subject: The folly of throwing the steering wheel over very far when making a turn, is well demonstrated by the preceeding paragraphs and it is right up to the good automobile

Digitized by Google

driver to keep as clear of this matter as he possibly can. This means, at all times, the turning of corners with the largest radius possible, the avoidance of any sharp turns whenever it is possible to do otherwise.

There is another thing which the driver may do, which will greatly lessen tire strain from turning the course of the car. This way may be called "modifying the turn" and it is founded upon the well known "modified curve" used upon all railroads where high speed trains are operated. To lay down a modified curve, the engineer first lays down the ordinary simple curve with a certain radius, never less than 3,000 feet, and as much more as possible, then he cuts out a portion of each end of the curve and puts in its place a short section of curve with a much greater radius. Next comes another short length

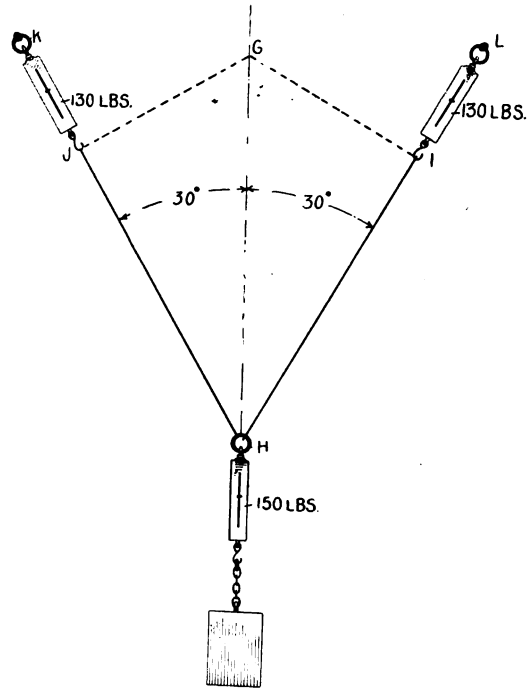

Fig. 5—The Parallelogram of Forces.

of curve with a lesser radius, and so on until it gradually gets down to the radius of the body of the curve.

The same thing is repeated at the ending of the curve, which grows flatter and flatter until the tangent as the straight track is called, has been reached. In this manner, the train is taken gradually from the straight track without the side-jerk which always is felt when a fast train takes a common curve, and which is repeated when the train reached straight track again.

The automobile driver can lessen the side strain by "modifying" the curve in the same manner as is done by the fast train. The driver can turn at a small angle and gradually throw the wheel over until the desired angle has been reached, thereby lessening the strain on the car which is given when a wide angle turn is made quickly and at high speed.

Probably the forward wheels of your car will not turn to form an angle of 60 degrees as shown by Fig. 4. But be this as it may, the wheels will turn to some angle and you can determine this and then make a diagram of it to see what pressure is put sidewise upon your automobile tires when you make a suddent start at that angle. In this way, you may get an idea of the limitations in this direction, of your particular car. And when you drive, and are called upon to make a sudden turn, be sure to keep as far from the limit as possible. The stress comes in two ways, not alone when you jump the car around from a standing position, but the same stress occurs, and to a much greater degree, when you suddenly swerve the car into a new course when it is moving at a high rate of speed. But the force will be much greater in this case, for, instead of having a few pounds stress to contend with—just the torque of the engine, you have the entire weight of the car at the rate of speed it may be traveling when the change of course is made.

This force is enormous as may be judged from the tipping over of cars which try to make short turns to avoid some person or obstacle. The overturning of racing cars illustrates this very point better than anything else and it is the cross-force which does the overturning, that corresponding to the 51 pounds and to the 130 pounds of Figs. 3 and 4. If these stresses come from 150 pounds of push, what must be the cross-stress developed when a car weighing a ton or more is swerved quickly when moving 60 miles an hour?

PROOF OF IMPROVEMENT.

A Test That Will Demonstrate How Much a Car Has Been Helped by Tuning Up.

From N. G. Near, New York.—Loose joints, tight joints, dirt, and insufficient lubrication are all consumers of extra energy in an automobile. Make the loose joints tighter, the tight joints looser, remove the dirt, and use enough of the right kind of lubricant and you may be pretty sure that the engine will deliver about as much power as it can reasonably be expected to deliver, granting, of course, that valve setting, timing, sparking, cooling, and other conditions are at their best.

A friend recently came to me with his car, which wasn't in very bad shape at the time—nor is it now—and asked if I could improve its condition and prove to him beyond a shadow of doubt that I had improved it. It set me a-pondering. I recalled the methods used by drivers in competitions where a gallon of gasoline must do maximum ton-mile work—where they coast at every opportunity. A well lubricated, properly adjusted automobile can certainly coast much farther than can one that is not so well groomed. I, therefore thought I saw my way clear to proving my overhauling ability and advised my friend to that effect, stipulating that he must follow my instructions and submit his car to a few simple friction coasting tests.

He agreed, and I at once climbed into his car and on the way to a suitable spot outside of town I unfolded my plan. We chose a hill that was not very high and that sloped gently to a long level stretch, about as indicated in the figure. The road was in good shape, the air was still, and everything was favorable for the tests. We drove the car up

Digitized by Google

the hill, turned around, and then began to descend at a very slow creep. We noted the point at which the descent was begun and thereafter began all descents from the same point. Power was cut off but the clutch was left in. The machine coasted down all right, but at a very slow rate. Before we reached the level stretch we had already come to a standstill. The engine had served as a pretty effective brake just as it is often made to serve when coasting down hill on regular pleasure rides. We marked the distance coasted with a small stake driven into the ground.

Then we climbed the hill again and tried it over with the clutch out. The machine coasted considerably farther, as expected. We drove a second stake at this point, and then tried both tests over again. The results were approximately as before. The stakes were not changed.

Then the car was driven back to the repair shop and we began work on it. Nothing out of the ordinary was done, except that I took particular pains to make everything as smooth-fitting and frictionless as possible. Engine, journals and ball bearings were all carefully inspected, cleaned, adjusted and oiled. Every repair man knows the regular course or the course that should be followed.

The Coasting Test.

By the time I had finished I was positive that the car had been bettered and that I could prove it.

After all parts had been assembled and I had given the car an initial try-out myself I drove to my friend's home and took him to the scene of the tests where I allowed him to handle the car as he did in the first test. This time the car not only coasted more rapidly with the engine "in," but it coasted considerably farther—much farther, in fact, in the second test with the clutch out. I didn't need to tell the owner that his car had been improved. He saw it. Road and weather conditions were practically the same as before. And when he noted how well the engine behaved under all speeds, loads and conditions he paid me a fee that was considerably larger than the fee I had intended to charge.

This method is far more satisfactory than watching the gasoline tank and computing the quantity of combustible consumed per mile, because the results here are visible and certain. In driving a car there are always the personal equation, speed, topography, etc., to be considered, whereas by coasting, with gasoline shut off, these factors are virtually eliminated. It is but logical that a good coasting automobile, with clutch in or out as above, should be economical with its gasoline.

Magnetos give a good spark when the engine is running fast, but for a hot spark when the engine is being turned over to start it the battery-delivered spark is usually the better. It gives even better sparks on slow than high speed, owing to better condenser action.

THE ROUND TABLE.

Practical Points for Driver, Garage and the Repair Man.

From G. D. Crain, Jr., Kentucky.—A tire dealer in an Ohio Valley city created considerable of a stir among motorists of that community, not to mention his competitors, when he announced some time ago that he would send out a man at any hour of the day or night within ten miles of his place of business to change a tire, charging at the rate of 40 cents an hour. The charge was so small, and the service loomed up as so attractive, that most of the car-owners in the city promptly took advantage of it. Even those whose cars were equipped with demountable rims did not always handle the change themselves, preferring, if the distance from the tire shop was not too great, to "let George do it." And there are a lot of cars running that have less convenient kinds of rims, and to their owners getting away from the labor and dirt of changing is a big relief.

The dealer found that the plan worked out so well that now he changes tires free of charge, if the tire happens to be the make which he handles. This is a big lever for business for that tire, because, other things being equal, the motorist will naturally prefer to have a tire which will insure free service of this kind. In this case the dealer figures that the amount of repairing which he gets, as well as sales of new cases and tubes, will more than pay the cost of maintaining the service. It seems to have worked out that way, and certainly his is the largest tire business in the town.

Another Tire Wrinkle.

A tire man who has a lot of business in connection with making changes for motorists who prefer to have him attend to this, rather than ruin their clothes and tempers, found that the time taken up in this work was chiefly consumed in inflating the tires after they had been put back on the rims. The tire men were equipped only with hand pumps, and in addition to taking up a lot of time it meant pretty hard labor for them.

He thought at first of equipping each of the autos which he used in this work with a special tire-pump, but inasmuch as he was also using a few specially equipped motorcycles, for which such an attachment could not be provided, he finally decided against this plan. The cost also seemed too large.

He finally met the problem, however, by simply putting a tank on each outfit and filling it with compressed air. The tire man thus carries his air to the job, and when he has made the change he can fill the tire in a few seconds, instead of having to go to the back-breaking task of pumping up by hand. And, of course, each member of the tire crew is capable of making a great many more changes than was formerly the case.

Digitized by Google

Will it Come to This?

An automobile man recently said that one of the developments of the business is likely to be the necessity of providing a car to take the place of that which is put in the shop for repairs. That is, he said, the owner who puts up his car will want to have another for use while his machine is being overhauled.

"It would surprise you," he said, "to know how owners delay having work done, because of the inconvenience to which they are subjected when they are without a motor car. Instead of being a pleasure proposition, the automobile has become an absolute necessity, and a great many business and professional men simply can't get along without them. The average man cannot afford to own two machines—though I know of some Ford owners who have adopted this plan—and hence this puts it up to the garage to supply a car for temporary use while the regular one is being put in condition."

In view of the large number of second-hand cars which are available at small cost, it seems as if this plan may be practicable, after all. And think how much business the garage man who advertised, "Leave Your Car With Us For Repairs—We Will Let You Use One of Ours in the Meantime," would get.

Everybody is familiar with the fact that most jewelers have watches, known as "loaners," which they provide while their customers' time-pieces are being put in condition. A closer analogy is found in the fact that electric supply houses must install motors to take the place of those which are out of commission in a manufacturing plant, and have to be withdrawn for repairs. The automobile is often just as necessary as an electric motor in a factory, so why should not some arrangement such as suggested be made?

In most cases, too, the dealer could get a reasonable amount for the use of his car, and thus be killing two birds with one stone.

Rehabilitating the Old Car.

The man who has to keep his old car, instead of being able to trade it in on a new one, sometimes gets dissatisfied with it, not because it is not performing its duty, but simply because he has tired of its appearance, and has become used to its familiar features.

If he can change its characteristics and give it a different appearance, he will get almost as much satisfaction out of it as though he had bought a new car.

A motorist who couldn't quite finance a new car this season spent about $200 on his old one, and now has a car that is the envy of many of his friends, some of whom are planning to emulate his example. In addition to a job of overhauling the motor and transmission, which put it in good running order, he had the car painted. Instead of making the color black, he changed it to yellow and black, a "loud" combination, but one which is far from unattractive. A new cover, of rough brown canvas, was then put on, and seat covers were supplied. All of the metal work was brass-plated, and the car was ready for business.

The owner has been more than pleased with the attention which his car has attracted, for in spite of the fact that it is a popular make, with scores just like it in the town, it takes a second or third look to determine just what it is.

A Bit of Carelessness.

Just because the operation of the speedometer is not necessary to the use of the car, a good many owners whose meters get out of condition fail to have the necessary repairs made. In fact, if one were to take a "work-needed" census of the cars in a community, it would be found that more speedometers required attention than any other feature of the equipment.

This is poor policy. The speedometer is not only necessary in order to insure keeping within the limit set by law, but it performs a very useful service otherwise. The careful owner keeps tab on his tire mileage by reference to the speedometer, and if this is not working all the time his records are of course incomplete and valueless. Then again, it is worth while to keep the meter operating so that in case the car is sold, the prospective user can be informed definitely how far it has been driven. While the total shown by the speedometer may not necessarily be correct, of course, it will carry weight when backed up by the personal assurance of the owner, especially if the latter is personally acquainted with the purchaser.

When a link in the cable breaks, and the speedometer quits registering, the car goes ahead, and the owner, if he is inclined to be careless, will pay no attention to it. But this is too important an item of equipment to do without, and the broken meter should be put in shape at the first opportunity.

Have You Changed Your Oil?

Changing the oil in the crank-case is desirable frequently, without reference to the season, if the car is to run smoothly and quietly all the time. But the change of seasons makes it especially advisable that this be done. If you have been using your oil during the past winter without emptying the case completely, do it now, and load up with clean, fresh lubricating material. It will help your car.

MORE ABOUT CLUTCHES.

Something About Lubrication, Cleaning, Slipping, And The Working Parts.

The multiple-disc clutch possesses some advantages over the leather-to-metal type. For example, where continual slipping would seriously damage the leather of a cone clutch, the increased surface of the multiple-disc clutch gives immunity from trouble in this respect. The fact that disc clutches operate in a dust-proof bath of oil is a feature that naturally tends to counteract tendencies of wear.

Although much might be said concerning the increased flexibility of modern engines and the decrease in the amount of clutch slipping necessary in ordinary driving, it is not intended to discuss the merits or demerits of either type but merely to draw attention to a few practical points connected with the care and upkeep of multiple-disc clutches, and to throw some light upon the various defects that are liable to occur in them.

The action of the type of clutch referred to is quite familiar, but in order to render the following remarks more clear, a section of a typical multiple-disc clutch is reproduced as Fig. 1. The flywheel is provided with a casing, in which longitudinal

Digitized by Google

grooves are cut, and an inner core having similar grooves is mounted on the clutch shaft. The clutch plates are provided with serrations, and being arranged in pairs, engage alternately with the grooves of the casing and those of the inner member respectively. A strong spring keeps the plates normally engaged through the medium of a suitably shaped part known as a presser. In order to give a certain amount of adjustment to the spring, a screwed cap is fitted to the cover of the clutch casing, and when set as required can be locked in position. The plates are operated by means of a fork, working on two projections of the actuator which also forms part of the clutch stop. Adjustment of the latter is secured by screwing the cone part shown in the illustration.

Lubrication of the Plates.

Many drivers have experienced how an overdose of even good quality of oil in the clutch casing will cause a considerable amount of slip between the plates, and at the same time prevent them from disengaging properly when the oil has cooled down. The usual practice is to mix kerosene with the oil in certain proportions, the latter depending upon the type of clutch and the material from which the plates are made. Almost every manufacturer has his own specific mixture for clutch lubrication, which can generally be relied upon to give the best all-around results, but it may be found necessary to thin the oil by the addition of small quantities of kerosene during the cold weather, in order to prevent the plates from sticking. To ensure that the lubricant is uniformly distributed over the entire working surfaces of the plates, holes are sometimes drilled through them, as in Fig. 2, and in cases where this refinement has been omitted the action of the clutch has often been considerably improved by taking out the plates and drilling them.

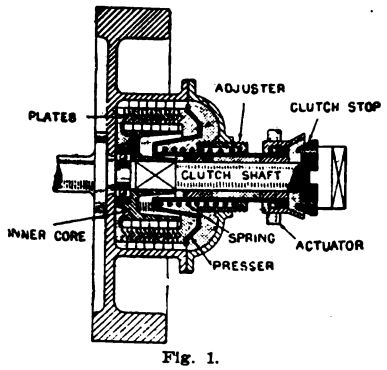

Fig. 1.

Great care, however, must be exercised in removing all traces of "burrs" left by the drill, as their presence would cause the plates to score directly the clutch was allowed to slip.

Cleaning Out The Clutch.

After the clutch has been in use for some time, minute particles of metal become detached from the plates as the result of wear, and on mixing with the lubricating oil these form a pasty substance, which, if allowed to remain in the clutch casing, would act as a very efficient grinding compound, with extremely deleterious results to the plates. Therefore it becomes necessary to wash out the interior of the casing from time to time, and afterwards pour in a fresh supply of oil. In addition to this precaution, it is highly desirable to take the clutch apart every few months, in order to clear out the interior of the casing more thoroughly, and also for the purpose of examining the condition of the plates.

Excessive Slip.

Should experiments with different kinds of lubricating oil fail to cure slipping plates, the adjustment of the spring cap may be altered to increase the compression of the spring, and so increase the friction on the plates. One should notice, too, whether the clutch shaft moves quite freely in a lateral direction, as any tightness caused by want of lubrication of this part has the effect of preventing the plates coming into close contact. If the above expedients do not put matters right, the clutch must be taken down for thorough examination by methods to be described.

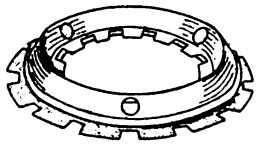

Fig. 2.

Dismantling.

One of the inconveniences in cars fitted with multiple-disc clutches is that the gearbox has to be removed from the chassis in order to give the necessary room for the withdrawal of the inner parts of the clutch. For this reason wear is often allowed to continue until the irregular action of the clutch renders driving extremely unpleasant, whereas a little attention given at the right time makes it easy to keep the clutch in good working order. Even if the amount of work necessary to get at the clutch is a drawback, it is false economy to delay attention to the plates on this account. Assuming that the gearbox has been removed, the clutch stop and actuator are taken off, after which the clutch shaft can be withdrawn. The next step consists of unbolting the cover of the clutch casing in order to expose the plates. Before all the bolts are removed, however, it is advisable to slack out the spring adjusting cap to its full extent, thus partially releasing the spring, for unless this point is observed the interior parts of the clutch may fly out suddenly as soon as the cover is released.

The clutch plates can now be slipped out of their grooves, and should be laid on one side in the order in which they are taken out.

The only part now remaining in the casing is the inner core, which can be drawn from the ball race by means of two hooked levers, the ends of which are inserted between the clutch casing and the back of the inner member.

Working Parts.

Having now taken the clutch to pieces, a careful examination of the working parts can be made, and attention is directed to the following points:—

The continual driving action of the plates causes slight depressions along the grooves of the clutch casing and those of the inner member. These depressions naturally hinder the free lateral movement of the plates, with the result that slipping takes place. The remedy for this defect is to ease the grooves by filing until the depressions disappear

Digitized by Google

entirely. The method of carrying out the latter operation is clearly shown in Fig. 3.

Each clutch plate should be examined separately, to ascertain the condition of its working surfaces, as even a slight amount of roughness on one plate will very soon spoil the other plates with which it comes into contact. When the defect is very marked the renewal of the affected plates is essential, and after considerable use it may be found necessary to replace as many as half a dozen or more plates in a single clutch.

Inattention to lubrication sometimes results in buckled plates, which may be largely responsible for the erratic action of the faulty clutch. Buckled plates can very frequently be straightened out by the careful use of a hammer and block of hard wood while the plate is laid flat upon a perfectly level surface.

Should any plates be neither scored nor buckled, one must exercise a certain amount of discretion in determining whether they have not worn so thin

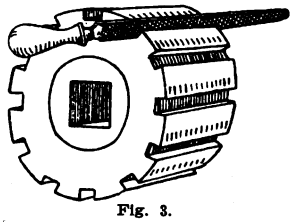

Fig. 3.

as to render them unreliable for further lengthy service, and it should be remembered that the cost of renewing a few plates is small compared with that of the time occupied in taking down the whole clutch to fit them afterwards.

These are sometimes used with the object of allowing the driver and driven plates to slip relatively to one another when the clutch pedal is depressed. One of the two types is generally employed—(a) spring separators and (b) stud separators—and while examining the plates one should take care to notice that none of the separators is missing, as they sometimes become detached from the plates and drop into inaccessible corners of the clutch casing and cause considerable inconvenience when the clutch is being assembled.

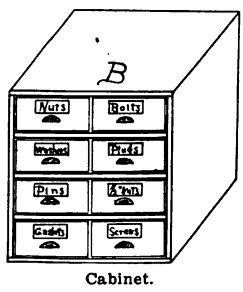
The condition of the ball race carrying one end of the inner member should not be overlooked, and if this part shows any signs of wear, the opportunity of effecting a renewal should be taken. One is sometimes apt to imagine that ball races situated in inaccessible positions are endowed with special immunity from the effects of wear and lack of lubrication, which is not the case and is liable to lead to very unlooked-for results.

Although the clutch shaft only revolves in its bearings when the pedal is depressed, the free movement of the former is a matter of no little importance and should receive due attention while the clutch parts are under examination.

There are one or two important points connected with the fitting of new plates that are worth special attention, and readers are warned against the prevalent practice of simply placing the new plates in the casing and assembling the clutch straightaway on the assumption that the new parts fit accurately.

In the first place the new plates should be tried separately in the grooves of the clutch casing as well as those in the inner member, and eased, if necessary, to give perfect freedom of lateral movement.

A further point requiring attention is that the new plates do not occupy more space than the old ones when originally fitted. As this is somewhat difficult to determine after the spring is placed in position the clutch should be temporarily fixed up minus the spring, when the amount of lateral movement on the clutch shaft will show whether sufficient clearance is allowed to permit the plates to slip when the pedal is fully depressed.



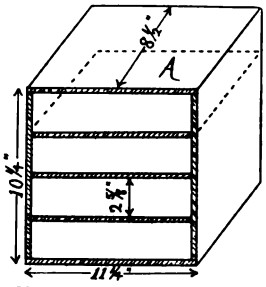
It has been stated on high authority that their ability to run smoothly when out of alignment is one of the great points in favor of multiple-disc clutches, but the writer has never come across a single instance where inaccurate alignment has not adversely affected the proper action of a clutch. On the contrary, in many cases irregularity of action has been completely cured merely by correcting the alignment, without making any other adjustments.

If careful attention has been given to the above-mentioned repairs and adjustments, little difficulty will be experienced in assembling the various parts of the clutch, with perhaps one exception, i. e., the replacement of the spring. Various appliances have been requisitioned for compressing the spring for the purpose of assembling, all more or less unsatisfactory and liable to allow the spring to jump out of position at the critical moment. A long stiff tube is slipped over the projecting end of the clutch shaft, and a plate having a 1 inch clearing hole is placed at the end. Through this hole a long bolt is passed and the head of the latter takes a purchase either against the cross member of the chassis or against a bar attached to the chassis for the purpose. When it is desired to compress the spring, the nut is screwed along the bolt until the two flanges of the clutch cover meet, when the bolts can be inserted and tightened up. This enables one to get over the difficulties usually associated with assembling this type of clutch, and the whole operation can be carried out in an extremely short space of time.

FOR THE SHOP.

A Cheap But Convenient Cabinet for Keeping Tools and Parts.

From C. P. Shattuck, M. E., Rhode Island.—In these days of keen competition among the garages



Cabinet.

and repair shops the saving of time is a factor in the bill rendered the customer. Considerable time is wasted in some repair shops in searching for a certain small tool or material, particularly if the parts are not systematically stored. Cabinets can be purchased, and some shops utilize those having drawers for the taps, reamers, drills, etc. The cabinet shown in the accompanying illustration was constructed by the writer for storing small material

Digitized by Google

and it proved so useful that a second one was made and fitted with a door and lock for securing small and valuable tools.

The cabinet shown consists of eight empty cigar boxes, but the number may be increased to 12 or 16 as desired, and a housing A which was constructed of whitewood. The boxes employed were 2¼ inches high, 5⅝ wide and 8½ long. As the width of two boxes was 11¼ it was an easy matter to ascertain the width of the cabinet. The ends of the boxes were planed flush with the sides and ¼ inch was allowed for each partition plus a trifle

Showing the Construction.

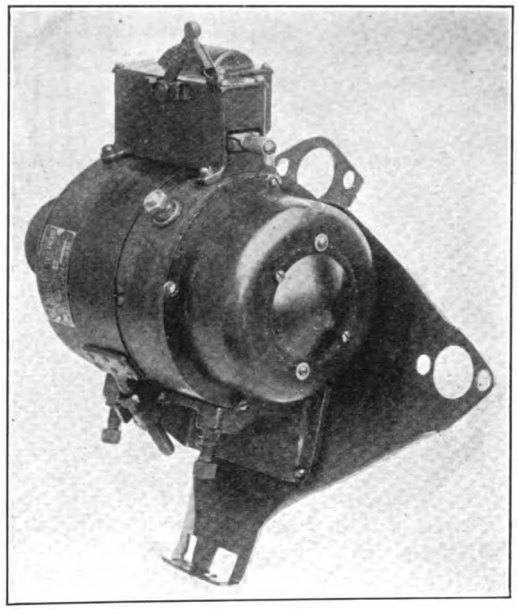
so that the boxes could be removed and replaced easily.

After the work was completed the cabinet was given a coat of shellac, then sandpapered to obtain a good surface, and varnished with a hard varnish. Ordinary handles or bales were attached to the boxes as shown at B, and each drawer was labeled. The second cabinet built was made slightly deeper and a door swung by using ordinary hinges. The cabinet was fitted with an ordinary hasp, and a padlock prevented tampering with the contents of the drawers.

It is not necessary to buy whitewood as a good packing box can be utilized if of the right dimensions. The cabinet is not only useful in the repair shop, but is a valuable and handy addition to the private garage, especially if two owners share the same garage.

THE GENEMOTOR.

The New Self-Starting And Lighting System Designed For Ford Cars.



A new self-starting and lighting system known as the Genemotor System has recently been designed and is now being manufactured by the General Electric Company, particularly for installation on Ford cars. The principal mechanism of the system consists of a single electrical unit, wound for twelve volts, which operates as a generator or a motor as the case may be, and the necessary accessories for attaching to and operating on the Ford car. In addition, a six-cell, 42 amp.-hr. battery is included. The outfit thus combines the functions of a generator, which furnishes the primary current required for starting the car and operating the head, side and tail lights, as well as those of a motor for spinning the engine.

The Genemotor is carefully enclosed, about ten inches long over all, seven inches in diameter, and weighs about fifty-two pounds. It is supported rigidly on the right-hand side of a Ford engine, viewed from the front, by a pressed steel bracket secured at three points. The installation is fully covered and protected by the engine hood when the latter is closed.

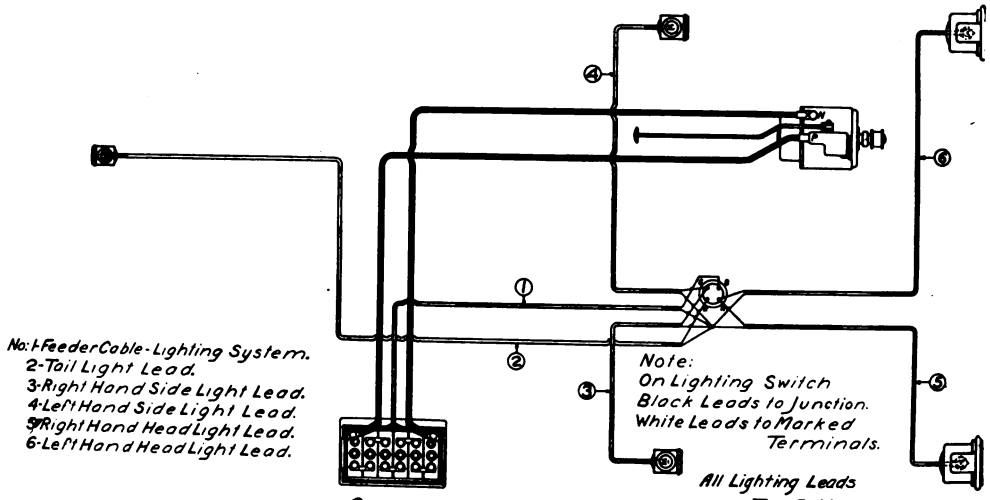
As a motor, the Genemotor will develop a torque of about 45 ft.-lb.; and the torque developed at the engine shaft by means of the selected gear ratio has been found amply adequate to start a Ford car under severe conditions of tight adjustments in the engine and cold weather. The storage battery is carried on the right-hand running board of the car, and is employed to accumulate current while the car is in motion for supplying the starting and lighting system when the car is at rest.

When the car has attained a speed of about eleven miles per hour, the Genemotor, acting as a generator, develops an electro-motive force sufficiently high to overcome the normal voltage of the battery and permit charging to take place. At this point, the reverse current relay operates, closing the circuit between the generator and battery, and charging begins at a low rate, the current gradually increasing as the speed of the car increases to a maximum of slightly over ten amperes.

A suitable steel procket is mounted on the engine shaft at the point where the crank is ordinarily applied. A steel pinion, mounted on the motor shaft, drives this sprocket and thus the engine through a silent chain of special design. The Genemotor is running either idle, as a motor, or as a generator, at all times while the engine is in motion, and thus all clutches can be eliminated. The fan is driven

The Genemotor.

by a belt from the Genemotor shaft pulley, mounted outside of the sprocket, to a split pulley provided for clamping onto the standard fan pulley.



The main switch and reverse current relay are mounted in an enclosed metallic case on top of the Genemotor and are readily accessible. The switch, which controls the motor, is closed through a cam actuated by a push rod extending through the dashboard of the car and terminating in a knob conveniently located near the steering wheel column.

Digitized by Google

The contacts are of the multiple leaf pattern and the switch is provided with a mechanism that assures a quick break on opening. The reverse current relay prevents current feeding back to the generator when the latter is operating at low speed or when the engine is not running.

The lighting switch, mounted on the dashboard at the right-hand side of the spark coil as one sits in the car, enables the side lights and tail light, head lights and tail light, or all, to be thrown on or off. It is applicable either to the straight dash or the new cowl hood dash on Ford cars. The wiring system is metallic throughout, no ground return being used. On the Sedan, Coupelet and 1915 models, the lighting switch is placed on the upper left-hand corner of the heel-board under the driver's seat.

The motor starts at once when the switch rod is pushed forward to make the switch contact, and the switch automatically opens when the push rod is released. Having ample power, it spins the Ford engine at high speed. Inasmuch as the Genemotor begins to charge the battery at the low car speed mentioned, the factor of economy is evident. When the engine stops, the reverse current relay automatically opens the battery circuit. The salient feature of the Genemotor is, therefore, its simplicity. It requires no attention from the driver other than a push with the foot to start the car and a twist of the switch to turn on the lights.

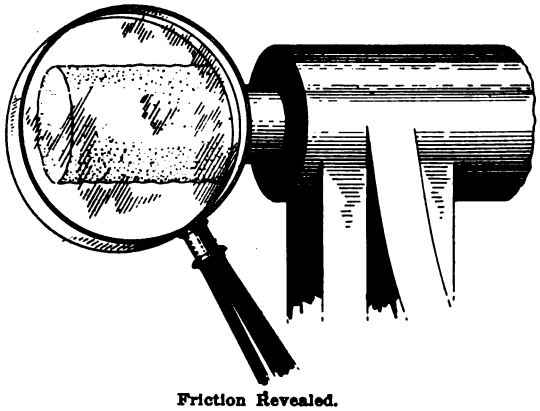
BEARING CARE.

Importance Of Correct Lubrication And Frequent Cleaning.



It will not take a long time to ruin a bearing if the conditions are right. And right conditions will be found in either faulty lubrication or neglect. Assuming that a bearing is not overloaded, and is correctly fitted in the first instance, this, of course, being the business of the car makers, the most important factor is the keeping of the bearing rigorously free from any grit or foreign matter, particularly metallic particles. Thus, great care must be taken that only a clean lubricant is used. Gearbox bearings are liable to suffer from metallic particles getting into the lubricant, these particles coming from the gearwheels in the normal conditions of working. This is one reason why a heavy gearbox lubricant is less preferable to a lighter one, which allows any heavy metallic particles to fall to the bottom of the gearbox. Even this does not altogether prevent the possibility of some of the particles being churned up with the lubricant, but it is less likely to happen with a light lubricant than a heavy one. Even so, it will be worth while to clean out the gearbox thoroughly at some period between 1,500 and 2,000 miles, and renew the lubricant. The illustration shows a bearing that to the naked eye seems perfectly smooth and in good condition. But if a magnifying glass be put upon it the defects appear instantly.

Any number of damaged bearings have resulted from the corrosion or pitting of the surfaces due to oil containing free acid. Rust is even more destructive to a ball bearing than acid or alkali in the lubricant, as it is far more rapid in its destructive action, and it is, in fact, the main adverse factor in the maintenance of a bearing that the makers lay most stress on. If the bearing could always remain in the same condition in which it leaves the maker's works it could never lose its frictionless qualities. There must, in a strictly scientific sense, be a little friction created by the lubricant as compared with a new, dry and polished bearing, but the latter, unless protected by the lubricant, would quickly be attacked by rust.

Wheel bearings obviously are from their position liable to the attacks of rust as the result of access of water during the washing-down process. For this reason it is most important to keep these bearings well packed with a heavy grease, and from time to time the hub caps should be removed and new grease forced in. Obviously such a bearing cannot run so freely as it otherwise would do, but the slight extra friction is of small account compared with the protection obtained. At the same time a

Digitized by Google

careful car owner will take precautions during the cleaning down of the car to keep water away from the bearings as much as possible. The makers do what is possible in the construction of the bearing to make it wetproof by the use of felt washers, but even this does not suffice against carelessness. The cleaning of bearings when fixed in the normal position is best effected by the injection of kerosene, meanwhile rotating the bearing and repeating the injection till the kero-

Friction Revealed.

sene runs off clean. In cases where the bearing can be detached, a method of cleaning advised by at least one large concern making ball bearings is to immerse them for a few minutes in a hot solution of washing soda, then in plenty of kerosene. The soda will effectively clean away all the solidified deposit and grit which is usually characteristic of much-used bearings.

GEAR RENEWALS.

More Trouble, Care and Work to Get a Fit Than May Be Imagined.

A new gear is seldom found to fit in an old gearbox accurately in every particular, and in many cases, unless a considerable amount of attention is given to the several processes of fitting the new parts, further renewals will become necessary in a remarkably short space of time. For the purpose of explanation, we will imagine that both the sliding gears of an ordinary four-speed selective type of gearbox require renewing and the replacements have been obtained from the manufacturers or their agents.

It must be clearly understood that such parts as gearwheels are turned out by automatic machinery, and after being subjected to the most minute examination, are sent out as interchangeable, that is so far as fitting with new gears is concerned, but, of course, this circumstance provides no guarantee that they will fit in gearboxes that have been subjected to great wear. Therefore it is quite reasonable to anticipate some adjustments, and even alterations, before the new parts will run accurately with the old components of the gearbox.

During the interval in which the car is out of commission pending the arrival of the new gears, the opportunity should be taken to clear out all the grease from the gearbox and remove such portions of the mechanism as may be necessary to facilitate fitting operations.

By passing the old grease through a piece of muslin, particles of metal from the gears will be noticed, thus giving a clue as to whether the damage has resulted from mere abrasion due to changing gear, or whether, on the other hand, the teeth have been subjected to more than the ordinary amount of wear and tear.

As a general rule the wear is not excessive on a sliding shaft, whether it be of the square or of the splined pattern, though it is advisable to see that no play exists in the bearings at each end, as the defect is frequently responsible for noisy gears. Any scoring or roughness on the working surface of the shaft should be eased down with emery cloth before attempting to fit the new gears.

It is quite common to find that a new gear will fit very tightly on the sliding shaft, a condition which, if allowed to pass uncorrected, would render the gears very difficult to operate, and most probably cause permanent distortion of the gear-operating mechanism. To enlarge the hole in the gear by means of filing is, of course, out of the question, owing to the hardness of the wheel, but a simple method of producing the same effect is shown in Fig. 1. The gear A, is clamped by means of straps B and bolts C, to a faceplate D of an ordinary lathe (recommended by reason of its convenience) a stout rubber pad, E, being interposed, as shown in the illustration. The hole F, to be enlarged is then filled with dilute sulphuric acid, made up of one part concentrated acid and two parts water, which is allowed to act upon the metal for about 30 minutes. At the

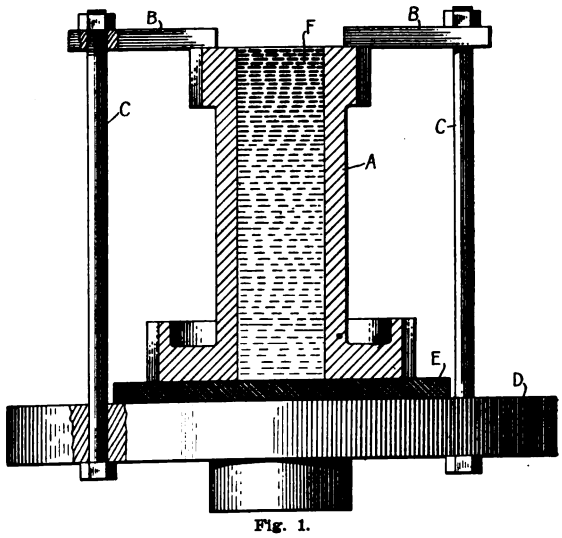


Fig. 1.

end of this time the acid is poured off and further corrosion may then be prevented by immersing the gear in a strong solution of ammonia, finally washing well in water. If the enlargement of the hole under the action of the acid is not sufficient to allow the gear to work freely on its shaft, the treatment may be continued as required. It is important to mention that sulphuric acid requires handling with very great care, by reason of its extremely corrosive nature. It attacks metal, fabric, wood, etc., and contact with same should be avoided. One of the most annoying experiences is to find that after new gears have been fitted, the car runs far more noisily than was previously the case. This often happens

Digitized by Google

when the circumferential mesh of the gears is inaccurate.

At first sight it appears somewhat difficult to improve gears in this particular, as in most gearboxes the relative position of the two shafts is unalterable. While the method of procedure recommended in this circumstance is perhaps a little unorthodox, it is preferable to the usual practice of allowing the gears

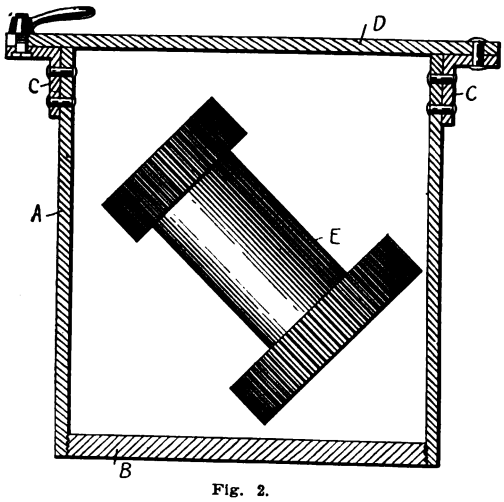

Fig. 2.

to wear in and so make it very easy for the ball races of the shafts and the other parts of the change-speed mechanism to wear out.

If the teeth of the gears engage too deeply with one another or are too thick on the pitch line, the only practical course to adopt is that of softening the gears and securing freedom of action by carefully easing the teeth. Particular attention must be paid to preserving the correct profile of the teeth during the operation, but to a skilful mechanic this presents no difficulty. On the completion of this part of the work, the gears may be run together and tested for silence, after which they must be rehardened.

Case-hardening Gears.

Many people who are fully conversant with case-hardening small parts such as pins and bolts, regard the same treatment for larger components as being shrouded in mystery; and in consequence have serious misgivings concerning attempts to harden gear-wheels. Successful hardening of the latter parts, however, merely entails the construction of some form of "muffle" which can be used in an ordinary forge, and attention to the simple precautions enumerated below.

Fig. 2 shows the construction of a muffle suitable for use in small garages and workshops where the quantity of hardening work does not justify the outlay necessary for the purchase of a gas furnace. A piece of steam pipe, A, of suitable diameter is screwed at one end to receive a bottom plate, B, and two lugs, C, are riveted to the top. The lugs form attachments for the lid, D, of the muffle which pivots horizontally, and by means of slotting the hole for the bolt, access to the interior can quickly be obtained.

The gear E to be hardened is placed inside the muffle and covered with special hardening compound. A forge can be used for raising the muffle and its contents to the required temperature, the effective heat being maintained for about half-an-hour per 1/16 inch of "case" required. After removing the muffle from the fire, the lid is immediately opened, the gear is taken out and cooled off by plunging it into clean, cold water.

Care should be exercised that the whole muffle is raised uniformly to a bright red heat, while it is equally important that no higher temperature should be reached, as otherwise the steel may become burnt and rendered brittle. If for any reason the gear cools down appreciably before being plunged, subsequent heating will be necessary before the cooling out is effected.

There are numerous grades of hardening mediums but in ordering the material one should specify the grade marketed for muffle hardening, as it differs slightly from that employed for the open-hearth process.

A simple test for ascertaining the depth to which the hardening effect has penetrated can be made by placing a piece of scrap mild steel in the muffle with the gear and cooling it out at the same time as the latter. By fracturing the test piece one is enabled to examine the nature of the hardened surface and thereby obtain some idea as to the wearing capabilities of the gears that have been treated.

Unless all the scale is carefully brushed out of the teeth of gears after the completion of the above process, there is a possibility of its working into the bearings of the gearbox. A stiff wire brush will be found very convenient for removing all traces of scale and superfluous hardening compound before commencing assembling operations.

Worn Jaw Clutches.

In many cases the jaw clutches of the direct drive become slightly rounded off at the point of engage-

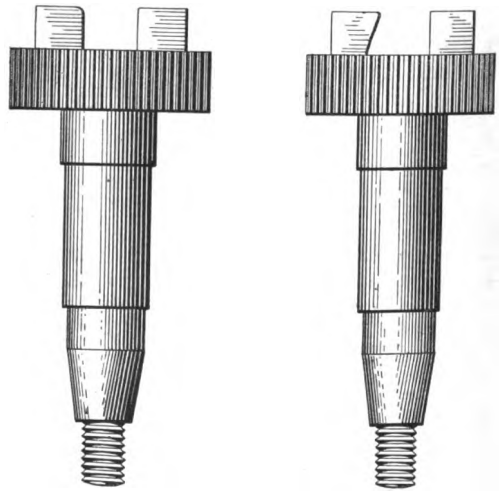

Fig. 3.

ment, and though this wear may not be sufficient to justify the renewal of this part, it is highly desirable that the fault should be rectified. A rounded jaw clutch, as shown at the left of Fig. 3, is very liable to cause the top gear to jump out of engagement at high speeds and damage the gears generally. The other part of the same Fig. shows the gear after having been undercut to prevent any possibility of involuntary disengagement. Each jaw must be cut

Digitized by Google

equally by means of a cold chisel, so that all engaging surfaces make proper contact with the jaws of the fellow gear, and the newly-fitted part must be re-hardened as already described.

The slight amount of backlash caused by the removal of the metal from the jaws in the way mentioned does not constitute a serious objection to this method of repair, especially when one considers the subsequent useful service obtained from a part that would otherwise have to be discarded as scrap.

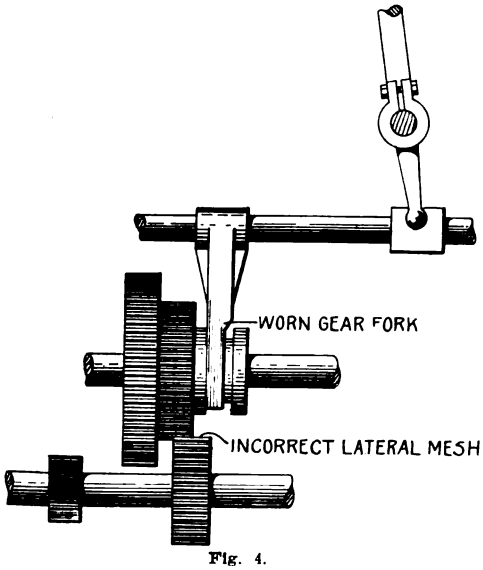

Fig. 4.

Reference to Fig. 4 will show a defect which is very common in gearboxes that have been subjected to considerable wear. It will be noted that, although the change-speed lever is brought to the limit of its movement in the gate, the pair of gears supposed to be in mesh are not fully so. This fault may give rise to several undesirable conditions in the gearbox, among which may be mentioned unequal wear on the gears, a tendency for all gears—the direct drive in particular—to jump out of mesh, and the possibility of the gears being partially engaged when the gear lever is in the neutral position. The latter constitutes a serious danger to the person who starts the engine of a car possessing this defect, as has been demonstrated with painful clearness on numerous occasions. The methods of adjusting the gears in this circumstance are dealt with in the following paragraphs.

Adjustment of Gear Forks.

The forks transmitting the lateral movement of the selector rods to the sliding gears are generally provided with a screw adjustment, by means of which it is easy to make any necessary alteration in the relative positions of the gears. This can be done by first setting the gears so as to give a good neutral, and then if there is a safe margin of movement on either side of the neutral, this margin may be used to any of the other gears that need lateral adjustment.

It sometimes happens that, although one or two sets of gear wheels mesh accurately when the gear lever is in its correct position respectively, the other gears may be considerably out of their true lateral mesh. To correct this fault it is necessary to alter the position of the notches of straight through quadrants, and to make similar provisions in the slots of gate quadrants. This is a matter in which little difficulty is experienced when once a clear idea is obtained as to the exact amount of alteration required.

Although the adjustment provided for altering the positions of the gear forks is extremely useful, it cannot, of course, be considered at all effective in taking up the backlash occasioned by wear on the gear-operating mechanism, as it merely has the effect of transferring the blacklash bodily to the new position. Therefore, it becomes very important to observe at which points backlash is likely to occur, with a view to securing a positive action of the parts affected.

One of the least desirable features connected with backlash in motor parts generally is the way in which it spreads like a disease over every moving part; thus to eliminate all slackness in the gear-operating mechanism, for example, by renewals would entail considerable expense.

Referring again to Fig. 4, the principal point at which backlash is liable to occur will be noticed. Commencing with the ball-ended selector lever, it is quite likely that the key securing this part to the change lever shaft may have become slightly worn, and even if the method of fixing shown in the illustration is adopted, readers are reminded that the mere tightening of the bolt will not effect a permanent cure without first renewing the worn key. The end of the lever engaging with the slot on the selector rod may also be slightly worn, and occasionally such wear, in addition to causing backlash, creates a "sticking" tendency while changing gear. The only practicable way of dealing with this part is to enlarge the worn end by swaging, filing up the ball to fit accurately in its groove, and afterwards draw out the lever to its original length.

Wear on the bushes of the selector rods may allow the latter to "kick" while being moved, which makes it difficult to change speed with ease. The worn bushes should be renewed while the gearbox is down for repairs. When the gear fork is worn, as shown in the illustration, Fig. 4, it is easy to see that quite an amount of waste movement is possible at the lever. In cases where it is not convenient to obtain a new fork and where the design of the latter will permit, the wear can be taken up either by fitting a strip of reinforcing metal or by drilling a number of holes to accommodate steel dowels let into the wearing surface of the fork.

Assembling the Gearbox.

Having given the necessary attention to the above points, the final assembling of the gearbox may be proceeded with. So far as possible, each part should be tested for accuracy and freedom of movement directly it is put in position, as, otherwise, it is difficult to locate any slight mal-adjustment when the whole of the mechanism is put together. Much time may frequently be wasted in taking down a gearbox to discover some trivial want of adjustment that could have been rectified in a minute had it been noticed at the proper time.

In conclusion, the desirability of assembling all parts with a liberal supply of lubricating oil may be emphasized, a factor which materially assists in giving the new and readjusted parts a fair start, and also tends generally towards obtaining satisfactory results.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1603 Magneto Trouble.

From G. S. Herbert, Missouri.—1—I have a low tension Splitdorf magneto, model F, and a coil which is not working right. I start the engine on dry batteries and then switch onto the magneto and it will run very well for a mile or two and stop. I then have to switch onto the batteries and speed up the engine for a short distance, then I can switch onto the magneto again. It will run very well for the rest of the day. It acts this way every day when I start out. Do you think weak magnets are the cause of this trouble? 2—Can magnets be tested without taking them off? 3—If the magnets were taken off of the magneto would that cause them to demagnetize? This magneto is on a 1913 model, 22 H. P., 4 cylinder Maxwell car, made by the Maxwell-Briscoe Co.

Reply.—1—The very fact that your engine runs satisfactorily on your battery of dry cells conclusively proves that your coil is not at fault. It looks very much as if your magnets were partially demagnetized, although your mixture may not be absolutely correct until after the engine is run a little while. 2—The strength of the current generated by the magneto can be tested without removing them. In fact, no one should consider attempting their removal unless fully qualified. 3—Yes, unless a keeper were properly used.

1604 A Good Record.

From James Flett, Iowa.—My Imperial car has run 8,000 miles since August 2, 1911, and during all that time the car has not been in the repair shop, except once a year to have the engine cleaned and spark plugs renewed. The car has been used on all kinds of roads through mud and sand and up and down some steep and very rough hills. I believe I wrote last year that the Goodrich tires which came with the car made a record of 5,000 miles before having to be renewed, and the last tire to wear out made a record of 6,500 miles before being renewed. I would like to hear from other owners of heavy cars in regard to these matters. My car weighs 2,900 pounds, empty. I am now using three Miller tires and one Goodyear and so far the Miller tires are giving the best of satisfaction. It is a comparatively new tire in this part of the country and I believe it is equal to the Goodyear or Goodrich. I see by your magazine there is quite a little discussion in regard to gasoline and cylinder oil. My experience has been that the best is the cheapest. I use gasoline testing 68, and the best cylinder oil I can get. 1—What is a good average distance for a quart of good oil to run the motor? 2—Does the use of low test gasoline and heavy cylinder oil have a tendency to make the motor smoke?

Reply.—1—It depends upon the oil, the motor and the speed of the motor. 2—Yes.

1605 A Question of Contract.

From C. O. Dawson, Kansas.—I used to run a garage and do auto repair work. Three years ago one C. A. Kenney came here and put in a garage and bought my tools and supplies and moved them to his garage. I agreed with C. A. Kenney to stay out of the automobile business for a term of five years. After selling out my automobile business I started up a machine shop.

Now, C. A. Kenney sold out his garage to Edward Gault, about 8 months ago. Can C. A. Kenney sign the above contract over to Edward Gault without my consent, and will it hold good to Gault? I claim it will not, on account that it was not made out to Kenney's heirs or assigns, and when Kenney sold out and quit business, I claim that released me from staying out of the auto business. About 4 months ago I sold my shop and the party I sold it to is doing repair work and handling two cars and I am working for him as a salesman. Gault has filed an injunction against me to stop me from selling automobiles. After I sold out to C. A. Kenney he brought automobile repair work to my shop that he could not do and I did it for him. He also brought automobiles to have them overhauled and tried to hire me to work for him. I claim he waived his contract here in hiring me to do this work for him. Gault has sued me for $1,000 damages, and while he has been here I have neither done repair work nor sold automobiles in Chetopa. If the contract will hold can he secure damages against me?

Reply.—The serious question for you is whether an injunction will issue restraining you from continuing your present employment. I don't believe that the provable damages will be large and quite likely that only nominal damages will be recoverable, especially as you have neither done repair work nor sold automobiles in Chetopa while Gault has been there.

I do believe, however, that an injunction will be granted against you. The contract is undoubtedly assignable, and would pass with the sale of Kenney's business to Gault. Your only hope, to my mind, is for you to show a waiver by Kenney of the condition of the contract. I do not think Kenney waived the negative covenants in the contract by bringing automobiles for you to repair and overhaul, as the covenant was "to stay out of the automobile business and not to work for anyone as repairman or salesman," the latter clause obviously would not apply to work you did as a machinist, working for yourself. "Not to work for anyone as repairman" clearly means that you were not to work as an employe, for any other man who might start an automobile business in Chetopa.

In order to show a waiver you must prove facts directly in conflict with the clear intent of the contract. You would have to prove that you worked as a repairman or salesman, as an employe, in Chetopa,

Digitized by Google

with the knowledge and acquiescence of C. A. Kenney after the contract in dispute was made with him.

1606 **Carburetor Trouble.**

From J. L. Pickles, Minnesota.—1—I have a 1913, Model T, Ford touring car, equipped with Holley carburetor, and am having a great deal of difficulty with my engine suddenly stopping on the road with no apparent cause, and I believe it is due to the small triangular intake valve sticking. This carburetor has been cleaned about ten times by various garage men and this valve has been ground in, but does not seem to remedy the matter. Sometimes the engine will pick up and run again before the car has lost its momentum; other times it is necessary to crank the car and it is a very difficult task to get it started. I have had three sets of coils, a master vibrator and a uni-coil outfit, without any results. When using the batteries I obtain very good spark in each plug. My car is very hard to start at all times, and when it is hot it is impossible to start it at all. Can you tell me why this is? The car has run 6,000 miles, was overhauled by maker this spring, and had new piston rings applied. 2—What voltage should I use in batteries in order that the adjustment of the coils would be proper for the magneto when adjusted to a good spark from the batteries?

Reply.—1—We are more inclined to the belief that your float is set too low and that too much rather than too little gasoline is being used, judging from what you say about it being hard to start the motor when warm. 2—Four dry cells should start it, giving you about 6 volts if connected, as they should be, in series, the carbon of one to the zinc of the next, etc.

1607 **Some Strange Questions.**

From W. P. S., Nebraska.—1—Please tell me the cause of a Ford car not wanting to start. I looked for the trouble a long time, but could not find it. Finally I put a little gas in one cylinder and that started it, and in a little while I heard something crack. At the same time I saw a big spark fly from the plug on top of the transmission. After that the engine ran faster. It has a Holley carburetor and a K. W. spark coil. 2—Do you think a master vibrator would make this car run better? 3—How is the best way to time the magneto—that is so the plugs would fire at the right time? 4—What causes the engine to skip 12 to 20 times in a mile run? 5—When the engine is taken apart, what would be the best way to take care of the magneto? 6—If I short-circuit one of the plugs with a screwdriver, or hold one of the vibrators down and the engine runs the same, what would be the trouble? 7—How would a car act if the magnets were discharged enough to bother? 8—What is the best way to repair a punctured condenser? 9—The valve stems and push rods have a clearance of two thicknesses of your magazine. That ought to be enough, it seems to me, but they click all the time. If there isn't hardly any clearance they won't click, but lots of power is lost. 10—What do you think ought to be done? 11—Why is it the engine will not start on half turns? It is even hard to start it turning the crank around, unless the wire that goes to the carburetor is pulled out. After getting it started it will run for a minute and then it will stop with the throttle open to the 3d, 4th and even 5th notch. When open at the 4th or 5th notch gasoline runs freely to the carburetor.

Reply.—1—Pretty hard to tell what is going on in the mind of any motor car. For this reason we are unable to answer your query, except we construe it rather differently, to which different construction we would have to reply that there are no end of reasons why any motor car will not start easily, or every time on the half, or even quarter turn—so many that we could not think of attempting to enumerate them. 2—If properly installed it should help the ordinary car equipped with a vibrating spark ignition system. Yours might be the extraordinary one, hence our care not to say that it will help "this car." 3—You cannot time the Ford magneto. The timer can be timed, and should be timed in strict accordance with the directions given in the Ford instruction book, which you should send to the Ford Magneto Co., Detroit, Mich., or the nearest Ford service station for, if you do not own one. Having secured it, study it and believe everything you read in it, even if some friend or enemy of yours tells you he knows more about Ford cars than Henry Ford and his entire engineering force, and can give him and them "cards and spades" on reliable information concerning Ford cars. 4—In addition to faulty ignition and imperfect carburetion, about forty-eleven primary, secondary and contributory other causes. 5—The best is never to take the magneto apart. 6—You might get a shock through the end of the screwdriver blade that would thoroughly awaken you. This should be trouble enough. It, in addition, would show that no explosions were occurring in that particular cylinder, or that the spark was occurring at the wrong time in the cycle, as would happen if you were to get two plug wires mixed. 7—By "discharged" we presume you intend to say demagnetized. In such condition the engine can rarely be started except on the battery, and it will run much better after it is started on the battery—but such conditions as mentioned are not conclusive proof of the demagnetization of the magnets, for they are but symptoms of other troubles. 8—Drown it, bury it, give it away, or otherwise effectively dispose of it. This is what coil manufacturers do with punctured condensers. 9—The various issues of this publication vary considerably in thickness. The thickness of two issues might be rather more or less than 7/16 inch. This seems slightly excessive when the rule is about two thicknesses of newspaper. We do not see how the push rods and valve stems get near enough together to click. If they do they should "holler," not click. 10—Let them click if you get any more power, unless you want to go to the expense of having the push rod guide holes bushed. 11—We once knew a motor car owner who, if our remembrance is correct, experienced similar trouble to this one you are trying to have explained away. After trying for several weeks he concluded that he would be satisfied if it started every alternate half revolution. This was several years ago. Periodically since he first noticed the motor's starting vagaries he has extended the starting limit—every third half turn, every fourth, fifth, etc., until now he claims he can start it sometimes on the 647th half turn, that once he secured its confidence he found it would eat out of his hand. The experience he gained before he

Digitized by Google

had won the motor's confidence he capitalized in connection with a badly run down ice cream business, and the patience he developed he hopes some day to put to commercial use, unless his motor should again bother him about starting when it may be worth even more to him for the pleasure of motoring.

1608 **Wrong Mixture.**

From Burpee L. Bishop, Nova Scotia.—My car is a 1912, Model T Ford, Holley carburetor, Ford coils and master coil. The engine runs beautifully and always has done so. Last summer the engine began to crank up bad in the morning. It would turn over a few times on one or two cylinders, and then stop. After repeating this quite a few times it would keep doing better until finally it would take hold and give no more trouble that day. This spring I have put on a new master coil but trouble is worse. If the car stands any time on the street, say five minutes, the engine may crank fairly easy but runs on one or two cylinders for perhaps ten revolutions, before it takes hold good. I have put in new batteries which I use in starting. My plugs are not new but they seem all right. Compression is fine. A few days ago I found I had a leaky carburetor, in fact enough to lose considerable gasoline, so I thought I had found my trouble at last. I overhauled the carburetor, shellacked the float and put it together. It is perfectly tight now and as far as I can find out does not flood. By removing the large screw over the float valve, no gasoline shows there. The old trouble, however, still continues, although I have not yet tried the engine under all conditions, hot, cold, etc., but as the engine stands cold in the garage I can see no difference. Does my carburetor need adjusting or do you think the trouble may be in the coils or plugs?

Reply.—It is quite evident from the symptoms described that you get either too lean or too rich a mixture when starting the engine. Your carburetor was designed for a much more easily vaporized fuel than is being marketed to-day, when the velocity of the air past the vaporizing nozzle did not have to be so high as at present. Later models of carburetors, Holley as well as others, have reduced area of free air opening. If your float is set too high there will be an excess of gasoline accumulate in a small puddle which the air may draw into the cylinders, making the gas temporarily too rich. The inlet valve stems may be so loose in their guides that air is drawn in to impoverish the mixture. If your cylinders choke with too rich a mixture it should result in a black, smoky exhaust. If the carburetor float valve should leak even slightly it would tend to choke the engine when starting. If on the other hand the mixture is too lean, contains too little gasoline vapor, there will be a tendency to backfires through the carburetor. The needle valve adjustment regulates the amount of gasoline used at intermediate and high speeds, in this carburetor, but it is easily affected by improper float level. From all of which you may be or should be able to divine the cause, too lean or too rich a mixture, and having proven this to your satisfaction you should be able to effect a cure. It is more than probable that very best results would follow the installation of the latest model of carburetor advised by the Ford Motor Co., although you may not find this necessary. We do not think your coils or plugs, or even the timer at fault, but it would not do any harm to clean the timer carefully and observe its condition.

1609 **Magneto Starting.**

From Dr. E. H. V. P., Washington.—I see that in No. 1554, on page 45 of the March number, what appears to me to be a wrong answer. A careful reading of the question leads me to believe that, instead of asking for means to utilize his low tension magneto for charging a storage battery, which in turn was to be used in connection with an electric starter, he really asked if the engine could not be started on the magneto instead of the battery. That is, could not the magneto be used to spark the engine in starting, instead of switching on his dry cells. If my surmise is correct, and it appears to be, your answer ought to have been different. I am using a car which is supplied with a low tension magneto, and a battery of four dry cells for starting purposes. Several times when my batteries had run down so low that they would not give a good spark, I have used the magneto for starting. This can be done if the spark is nearly fully advanced, and the switch on the magneto side, by spinning the engine by hand, after priming the carburetor. Will you please look up this matter again for the gentleman, as he will evidently not be satisfied with your answer if I am correct in my judgment as to what he wished to know.

Reply.—Our understanding of the information desired by our correspondent, whose letter was considerably abbreviated after the reply was written, was whether it were possible to use a low tension Splitdorf magneto for electric starting, but in case he referred to ordinary starting we included in our reply to No. 2 query the following: "There are some engines that are so structurally designed that it is well nigh impossible to start with a magneto," which should have given him the desired information. We are glad to have you call our attention to anything that does not seem fully explanatory or fully understood. Your method of starting on the magneto is the one usually employed. There are motors on the market designed not to be started on the magneto. In such cases the magneto is so timed that on late setting of the ignition the break will occur after the "peak" of the alternation, or when the current is considerably weaker than when advanced as for ordinary running. Such a motor might start easily on a battery and extremely hard on the magneto, in such a case it being practically an impossibility to start on the magneto except one were possessed of extraordinary strength, with the particular knack of doing it. On the other hand there are motors equipped with easy starting magnetos (higher priced usually) on which the motor may start more easily than on battery.

1610 **Rear Cylinders Miss.**

From Reader, Wisconsin.—I have a 40 H. P. Kissel car, 1909 model, equipped with Remy magneto and coil, Stromberg carburetor with water jacket. I purchased this car second-hand three years ago, and have run it about 2,500 miles. It ran fine until one year ago when it began missing on the two rear cylinders. The reason it misses is from spark

Digitized by Google

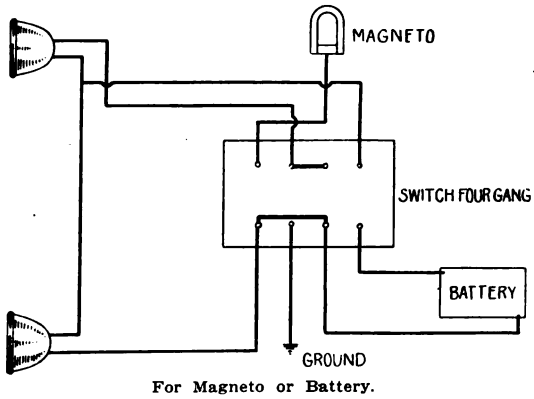
plugs becoming coated with a rather dry, black soot. After cleaning the plugs it runs good for a half a mile or so, when it begins missing again. The valve stems are slightly worn. The cylinders are smooth, and the rings appear to be good. The oiling system consists of a pump forcing oil through tubes to each cylinder. I have carried oil in the crank case very low with no result. 1—When the magneto breaks the primary circuit, a spark occurs at the breaker points. Is this due to a poor coil? 2—I start the engine with four dry cells. The engine works better with the battery than with the magneto when running slowly. The magneto has a stationary coil, no brushes. Can I test the same by connecting an ordinary battery tester in the magneto circuit, while running the engine on the batteries? 3—If leakage past the pistons causes my engine trouble, can it be remedied by replacing the old rings with Leak-Proof rings, advertised in your paper? Any information on why the spark plugs foul in my engine will be much appreciated.

Reply.—1—The sparking at the breaker contact points is not due to the condition of the coil, except the sparking occurs when running on the battery, for the coil is not used in the magneto circuit, and is only used with the battery circuit. 2—You cannot and should not attempt to test the magneto circuit by means of the battery tester. Our advice to you is to send the magneto and coil both to the Remy Magneto Co., Anderson, Ind., for a thorough overhaul. 3—If there are slight leaks, and the cylinders are not scored or badly worn, and the pistons do not fit too loosely, you may be able to secure an improvement by fitting new rings as you suggest, but the chances are that an engine like yours, now six or seven years old, will need much more heroic treatment—reground cylinders, new pistons and newly fitted rings. Machine shops equipped to do this work usually charge about $10 each cylinder. There is no question in our minds of the cause of the sooting of the plugs—the worn condition of cylinders, pistons and rings.

1611 **A Slipping Gear.**

From D. C. Butler, Oregon.—I have a Reo car, model 1912. The intermediate gear slips on my car when I go up hill. The other gear doesn't slip; if I hold the intermediate gear it pulls all right. Do you think it hurt the car to hold the gear in place? I took it to a garage and they said they could fix it but I could see no change so I would not let them experiment with it. I think maybe it is not adjusted right. Could you give me some information as to what the trouble could be?

Reply.—Failure to keep gear in is in all probability due to wear. It will probably necessitate new parts to replace worn ones, bushings most likely. The harm already having been done we do not see how any further injury could result from holding the gear in place by means of the speed lever. We have told you what the trouble might be, but what it could be is too much of a proposition for us to attempt to solve in the limited space allowed for this reply.



1612 **A Carburetor Problem.**

From Joe Halda, Kansas.—Some time ago I was called out to fix a machine that died on the road, and when I got there I found that the carburetor was flooded, and there was no way to drain the carburetor. Finally I took a spark plug out and primed it and the engine would run as long as the priming would last. Then I took a small plug out of a manifold pipe and put it in the oil can with some gasoline and turned the engine over. It would run as long as the gasoline would last. What would you think would be the trouble with the machine?

Reply.—The trouble was directly caused by a failure to get sufficient gas of the proper proportion of air and gasoline vapor. While this answers your query as you have put it, you probably would like to know what could cause such a condition. There are very many possible causes, such as dirt, water, air-bound tanks, empty gasoline tanks, closed valves, air leaks around the inlet valve stems, waste or old cloths in the air inlet, broken auxiliary air valve springs, stuck air valves, and a few score or so more. This reply of ours we know will not interest our readers nearly as much as would your telling of the cause of failure to get gas, provided the cause were an unusual one.

A Lighting Diagram.

From Earl J. Van Sciver, New Jersey.—Having read with interest article No. 1601 of J. A. Mandel, in the April issue of your magazine, I beg to offer the enclosed wiring diagram which I have found to be entirely efficient. By using a six volt battery and lamps and using a four gang switch, I am able to change the wiring system from parallel to series at will. The top two switches are used for dynamo lighting and the bottom two for battery lighting. While this looks very complicated at first, it is in reality very simple, although I admit that it took me several hours to figure it out.

For Magneto or Battery.

An Elusive Trouble.

From Lyman Fisher, Massachusetts.—I have driven an Overland car, model 52, 1911, which I bought second-hand in the fall of 1911. The car had been driven hard and abused in repairing, but was in pretty good running order. I did some repairing upon it myself and then took it to the Overland Company and they did more work on it when my troubles ceased until this spring when it began to lose power. It would run fine when standing, but when I went to start the power it was not there. Finally it would not pull at all. Experts said it was due to carbon. I had the valves reground and the

Digitized by Google

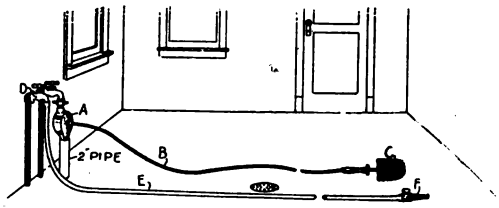
magneto made over, but it only made matters worse. Then the wiseacres laid it to the carburetor and I had that tested and found it was all right. I finally took it to an expert and learned that the cap on the valve spring had become worn and let the pin through. This was fixed and it then ran all right. The cap that caused all the trouble cost 6 cents. It took 19 hours of labor to find out the cause. Before it was fixed one gallon of gasoline would run the car three miles. Afterwards one gallon of gasoline ran it 16 miles with many stops. The car weighs 3,400 pounds. It now runs better and has more power than it has had since I bought it. When the cold weather came last fall I tried to start the engine and took three-quarters of an hour to get it running. The gasoline I used tested only 58 degrees. I then went to Boston and bought a barrel of 73 to 76 degree gasoline and started the engine in five minutes. I had no more trouble with starting until I was out of that high test gasoline. I have concluded that it is no use to use ordinary automobile gasoline in cold weather.

Leaking Grease.

From W. B. C., California.—I would like to say a few words about the leaking of grease from gear boxes and rear ends. If the various parties that are having this trouble would clean out the grease and use a heavy body oil instead (something like 600 W, or lighter) there would be less noise from gear boxes and fewer burned and cut driving pinions. The average person, when the grease begins to leak rushes to get some heavier oil. The reason that the grease runs out and the oil does not is simple. The centrifugal force of the gears throws the grease to the sides and top of the case. It becomes plastered tightly all over the inside and is not on the gears where it should be. As soon as the gears have thrown off the grease there is an abnormal amount of heat generated which expands the air and causes the grease to be forced out. When oil is used, and a pound of flake graphite to the gallon of oil, it is a great help. It is taken up by the gears and thrown all over the case, but not like the grease, it does not stick but drips down again and keeps a steady flow of oil on the gears. There is less heating, the gears are always lubricated and when the air does become warm it can flow out beside the shaft and does not drive the grease ahead of it.

Two-Point Plugs.

From W. B. C., California.—In answer to E. S. Richardson, 1580, who asks about two-point spark plugs, I would say that I have Su-Dig plugs in series with Ezekleens on my Maxwell 30, which is also a T head motor, and would not remove them for any price. There is far more current generated by the present day magneto than can possibly be used in a single plug, and the double ignition is a great saver of gas, as well as less gear shifting and more speed. My observations lead me to believe that there is also less heating.



How to Make Tires Last Longer.

The deterioration of a casing should be confined to wear of the tread rubber. Proper inflation will do away with much trouble from rim cuts, and unnecessary bending of the fabric. As long as the fabric, the sinew of the tire, is covered by the waterproof rubber, it remains practically as good as new. But instead of wearing away evenly, the tread is often cut and chipped by sharp stones, glass and ruts. Dirt and water are forced into the cuts, then ground into the fabric with enormous pressure. A sand pocket results; then a blowout that ruins casing and tube. Not one tire in a hundred but fails from just this cause before it has given half its possible mileage. Any good tire should run ten thousand miles or more, if the cuts are sealed before the fabric is injured.

A good vulcanizer will mend casing cuts permanently while the tire is inflated on the car. First the cut is filled with crude Para rubber which can be obtained from any garage. Then heat is applied with the vulcanizer which is simply clamped on the tire, and heated with gasoline, steam or city lighting current. If the temperature is controlled automatically, no watching or regulating is required and there is no danger to the tire so that any motorist or chauffeur can vulcanize as well as an expert. Tubes are permanently mended in about the same way in less time than it takes to stick on a temporary patch. Thus by giving tires only a little attention their mileage can be doubled or trebled, upkeep expense eliminated, and roadside delay due to blowouts can be avoided.

A Car Washer.

The labor of washing an automobile is reduced by a device, shown in the illustration, combining a

Water Motor Car Cleaner.

hose and a revolving brush. At A in the illustration is a four inch water motor connected to a common water faucet. B is a flexible shaft, connected to the shaft of the motor, with a revolving brush at the other end as shown at C. There is also another faucet, D, to which an ordinary garden hose, E, is attached with a nozzle, F. In connection with the motor is a two inch pipe which serves as a drain pipe to connect with the drain of the garage. The mud, etc., is first softened and loosened by the water from the hose, E, without using the brush, C. Then after this is completed the brush is used on the car and assisted by the hose. This car washer can be placed in a garage at a small cost and will save time and thoroughly clean the car.

Good Tire Record.

From George A. Bailey, Michigan.—I have been reading your Trouble Department for five years from which I have received much benefit. So never had any trouble. I go out right and come home right. I bought a Jackson car five years ago last October, fitted with Fisk demountable rims, bolted on tires. I have run this car 9,000 miles without having any trouble, and it is still on the original tires. I got my first puncture at 9,520 miles. Some good luck, I reckon.

Starting the Studebaker.

From O. E. Kennedy, Pennsylvania.—Regarding trouble question No. 1554, from "Reader, West Virginia," have you answered the question correctly? In reply to "Reader's" question desire to say I own a Studebaker 25, equipped with Splitdorf low tension dual ignition system. With this system you can start on the battery or magneto. In fact I have not carried a battery this winter. When starting on the battery, the spark lever should be well back or retarded from the running position to avoid any possible kicks. To start on the magneto, advance the spark lever to a point slightly above the running position. Spin the engine and you will find it will start easily, or should, providing the contact points on the magneto breaker box are in good shape. A five-cent nail file is a good tool to keep handy for filing platinum points on the breaker contacts. Do this operation gently or the platinum will soon be worn away. After smoothing up the platinum points so they are nice and smooth, they should be adjusted to separate at the furthermost point, not more than the thickness of a smooth dime. If the nail file you have is the thin model kind, the smooth end can be used for a measure to adjust the contact points. The engine should start cold on one-half turn, or when warm on one-quarter turn. There is no easier starting engine made than the Studebaker when mixture, spark plugs, etc., are in good shape.

The Metz Friction Drive.

From C. A. Stone, Iowa.—I have had all kinds of trouble with my 1913 Metz car. I never saw a nicer running engine, but that slipping drive was the trouble. Now that I have located that, it is no trouble for me to go any place, I don't care how steep the hills are. I draw 128 miles on 4 gallons of gasoline. I think you will find the answer to your slipping clutch all wrong, as a heavier clutch spring would not do. Now a friction drive will hold and do good work, but there is one thing that has to be done and that is to have the fiber wheel cover square against the disk. I think if you line up your wheels you will find the right hind one runs ahead and that is a sign that your frame is out of square. This is caused by the fiber running on the left side and pushing back on the frame with nothing to hold it. Then it is impossible to adjust the same so it will not slip. Now I braced the left side of the frame and put a jack screw on the right side and pushed it back until my wheels were lined up. Then I braced the frame by crossing the braces under the frame behind the dust pan. Then I crossed the corners of the frame with some short braces. Put your control lever on reverse, then adjust the disk so it is the same distance from the fiber wheel on reverse as it is on high and you will have no more trouble with a slipping clutch. I often wonder why the Metz Company do not brace their frames better, because a frame out of square on a friction driven car is going to give all kinds of trouble and is hard to locate.

Sticking pedals may cause you to run into some obstacle. A small piece of rubber fastened to the under side of the foot boards where it will act as a bumper for the pedal will remedy the trouble.

A Broken Driving Lever.

For one reason or another the controlling lever occasionally breaks. When this occurs it may be mended as follows:

Take a piece of metal, A, as shown in Fig. 1, and

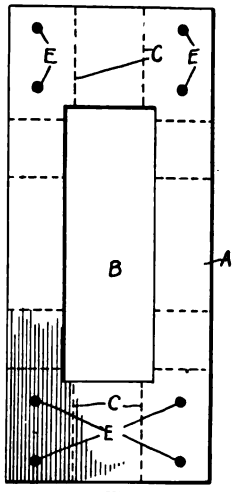

Fig. 1.

cut a slot, B. Then bend on the dotted lines, C. Now place A on the lever, D, as shown in Fig. 2, and hammer it to shape as shown. Drill eight holes, E,

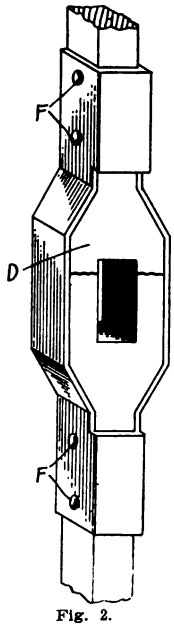

Fig. 2.

to receive the rivets, F. When finished the lever will be found as strong as ever. The lever shown is one that works on a quadrant.

Signal Horn and Magneto.

From Chas. S. Topping, California.—I have an electric horn that operates on the Ford magneto. It gives perfect satisfaction and has been in use two or more years. It is the Dean Ford Horn, Chicago, Ill.

(Note—This horn is now made by the Garford Mfg. Co., Elyria, Ohio.)

Digitized by Google

BOSCH SYSTEM FOR FORDS.

Claims of More Power, Greater Speed and a Better Running Engine.

The Bosch Magneto Company now provides special ignition outfits in two forms, gear driven and chain driven, for equipping Ford cars. The gear driven attachment is the one most in favor. This ignition outfit will be attached by any of the representatives of the Bosch Magneto Company at a nominal charge. Practically any garage can fit the attachment and in fact if one be needed, with ordinary tools he will be successful in installing it. The following instructions for installing the gear driven attachment are taken from the Bosch Magneto Company's catalog, although the matter is somewhat condensed.

The first procedure includes removing the hood, draining the water from the radiator, removing the coils from the dashboard and loosening the holding nut of the radiator rod at the radiator end. After detaching the water inlet and outlet connections A, at the engine and disconnecting the priming wire, as well as the gas or electric connections to the headlights, the radiator itself is to be lifted off and the fan assembly and belt removed, leaving the forward end of the engine clear as shown at B, Fig. 1.

Next to be removed are the actuating rod leading from the foot of the steering column to the timer, the bolt and spring holding the timer in place and the timer case with contacts, as well as the wires leading thereto, all of which may be discarded. The hexagon headed nut, washer and cotter pin holding the timer brush assembly are to be removed and the arm and roller pried off with a screwdriver.

The cotter pin at each end of the crank shaft starting pin, on the inside of the lower fan pulley, is to be withdrawn and the pin itself driven out through the opening in the engine support. The starting handle or crank is then to be removed and the lower fan pulley pried loose by means of two screwdrivers placed behind it, one on each side. In order that the fan belt may clear the Bosch gear housing, a new fan drive pulley is to be substituted for the old one and the original crank shaft starting pin, with cotter pin at each end, is to be used to secure it in place. Should the ends of the pin project beyond the rim of the new pulley they are to be filed down flush. The fan belt and starting crank are then to be replaced.

The key for the large Bosch gear is to be set in place on the cam shaft after first enlarging the hole in the protruding end of the shaft by means of the 5/32 inch drill furnished with the attachment. Any burr left by the drill is to be filed down before placing the key in position.

The second and third bolts holding the crank case on the valve side of the engine are to be removed, also the cylinder front cover tap bolt immediately to the right of the cam shaft. The three bolts, two vertical and one horizontal, at the base of the cylinder front cover and to the left of the starting crank, are to be removed and their heads ground down about half way so as not to interfere with the placing of the Bosch gear housing.

In order to provide sufficient clearance for the idler section of the Bosch gear housing, an opening about 2 by 3 inches is to be cut in the engine pan directly beneath the housing, the exact location and size of the opening being determined by applying the housing loosely to the engine, first, however, attaching to the housing the magneto supporting bracket, using for the purpose the two hexagon headed cap screws and washers. The positions of the four bolts securing the magneto to its supporting bracket are to be marked off on the engine pan and a hole about an inch square cut at each point so that the magneto may be removed at any time after completion of the installation merely by disconnecting the coupling and withdrawing the four magneto bolts. The cutting of the openings in the pan may be done with hammer and cold chisel and an ordinary jack used to support the pan during the operation.

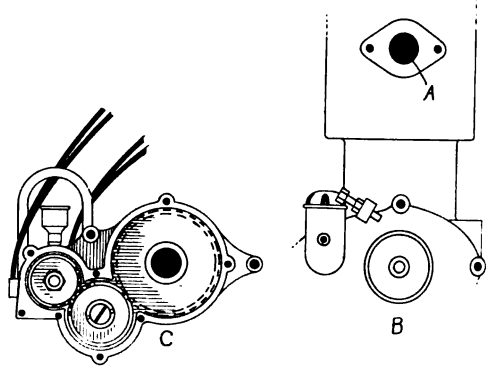

Fig. 1—Gear Driven Attachment.

If these details are properly executed the gear housing and magneto bracket should drop readily into position. This being assured, the magneto end of the coupling is to be secured to the magneto shaft by means of the nut, washer, and crescent shaped Woodruff key accompanying the magneto. The magneto is to be secured to its supporting bracket by the four bolts, which lock washers, and the magneto end of the coupling is to be connected with the bolt end of the coupling, by means of the four slotted hexagon headed bolts and leather center coupling piece.

In assembling the coupling, it should be remembered that the leather center piece is intended to afford a flexible drive from the gears to the magneto, so as to compensate for any slight irregularities in alignment. In order to secure the flexible drive effect, however, the two flanges of each coupling end must be bolted directly to the leather center piece at right angles to each other or, in other words, the flanged ends must be set crosswise one to the other, using all four bolts provided for the purpose. Under no circumstances should the flanges of the two coupling ends be bolted directly together, i. e., in a straight line using only two bolts, as such an arrangement would give a rigid, not a flexible drive.

The Bosch gear housing cover and large gear are then to be removed and the entire attachment mounted on the engine and held loosely by the four supporting belts.

It is possible that slight inequalities in the engine casting may interfere with the proper alignment of the Bosch outfit, so that special care is to be taken that both lugs of the magneto bracket bear on the flange of the crank case and that the two holes in the bracket lugs register with those in the crank

Digitized by Google

case flange. Any irregularities which exist may be readily corrected by slightly filing the face of the Ford oil cup casting (or the shoulder of the Bosch gear housing resting thereon), or by placing washers under both lugs of the magneto bracket. C shows the gear driven attachment ready to go on B.

The dust cover over the magneto armature, also the slipring brush holder farthest from the engine, are now to be removed and the piston of No. 1 cylinder (that nearest the radiator) brought on top dead center of the compression stroke and maintained so. The magneto armature is to be turned by hand, by means of its coupling, in the direction in which it is to be driven until, first, the metal slipring segment is visible in the slipring groove corresponding to the figure "1" of the brushholder which has been removed and, second, the trailing end of the armature is about 9/16 inch from the pole shoe on the right side of the magneto, viewed from the shaft end. With the armature held in this position, the large gear is to be slipped into place on the camshaft and meshed with idler gear, care being taken to see that the piston of No. 1 cylinder has not moved from the top dead center position.

It is important that the gears should not mesh too tightly and, after tightening both bolts supporting the housing, it should be seen that there is approximately the same play between the large gear and the idler gear as between the idler and the small magneto gear. In case the large gear meshes too tightly the two bolts supporting the gear housing should again be loosened and the entire housing shifted slightly to the left, which may be done quite readily as the two bolt holes in the gear housing are a trifle oversize. In like manner, the housing should be shifted slightly to the right in case it is found that the gears mesh too loosely.

With the adjustment of the gears correct, the two gear housing supporting bolts, as well as the two bolts securing the magneto bracket to the crank case, are to be permanently tightened, using for the

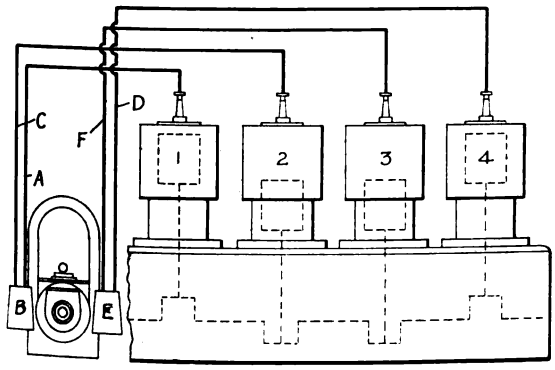

Fig. 2—Wiring Diagram.

two bracket bolts the original Ford nuts and new lock washers. The original nut and washer are also used on the end of the camshaft to retain the large gear.

The gear housing is to be packed with a good quality grease or non-fluid oil and, after carefully fitting the paper gasket, the gear housing cover is to be secured in place. During operation, the grease cup of the Bosch gear housing should be given a turn every day and the cup itself filled with grease whenever oil is supplied to the oil cup on the Ford cylinder front cover. The slipring brushholder and the dust cover over the magneto armature are to be replaced and the four high tension cables connected as follows:

The cable marked A, in the brushholder B, is to be connected to number 1 cylinder, while the cable marked C in the same brushholder is to be connected to number 2 cylinder. The cable marked D, in the brushholder E, is to be connected to number 4 cylinder, while the cable marked F, in the same

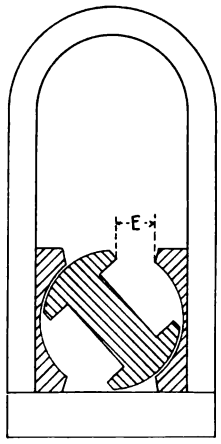

Fig. 3—Timing the Magneto.

brushholder is to be connected to number 3 cylinder. The firing order of the Ford engine is 1, 2, 4, 3.

All cables are to be led under the arch of the magneto magnets and through the cable guide, supported by the bracket, the latter being secured to the engine by means of the middle cylinder head bolt on the magneto side.

After engaging the short connecting rod with the arm of the interrupter housing and securing it in place by means of washer and cotter pin, the advance bracket is to be set across the first two studs holding the inlet and exhaust pipe clamps and is secured to the clamps with the orginal nuts. If necessary, the shoulders of both clamps are to be filed down to permit the nuts to fasten properly on the studs. The long connecting rod passing across the front of the engine, is to be engaged with the ball joint at the foot of the steering column to which the timer rod was originally connected.

The fan, pulley assembly and belt are to be replaced in their former position, after first placing the spacing washer in back of the driven fan pulley to align it with the pulley on the crank shaft. The face of the hole in the dashboard through which the radiator rod passes is to be slightly countersunk to receive the head of the rod and permit the metal plate to set snugly against the dash, covering the holes left by the coil box. The Bosch key switch is also to be fitted and connected. The radiator is to be returned to place and all bolts securing it and its water inlet and outlet connections tightened up, first, however, applying a coat of shellac or white lead to the gasket between the water connections and the engine. After refilling the radiator the engine may be started and tested and, if O. K., the gas connections to the headlights are to be replaced.

During the engine test, the operation of the gears, especially, should be noted. If, during operation, the gears give rise to a high pitched ring, the indications are that they have been meshed too tightly, while a

Digitized by Google

rattling noise indicates gears meshed too loosely. Either condition should not be allowed to continue but should be corrected.

In timing the magneto for Ford cars, the magneto armature is to be turned by hand, by means of its coupling, in the direction in which it is to be driven until, first, the metal slipring segment is visible in the slipring groove. Second, the trailing end of the armature is about 9/16 inch from the pole shoe on the right side of magneto, viewed from the shaft end. The 9/16 inch distance should be measured as shown by the letter E in the illustration shown. With the armature held in this position, the larger gear is to be slipped into place on the camshaft and meshed with the idler gear, care being taken to see that the piston of No. 1 cylinder has not moved from the top dead center position.

Danger in Oxygen.

From A. Cressy Morrison, New York.—I notice in your Trouble Department, April, 1915 issue, page 49, No. 1587, entitled "Oxygen for Carbon Cleaning," Newell F. Resseguie asks if anyone has tried cleaning carbon from an engine by running it and feeding it a little oxygen gas at the same time. He adds, "if this oxygen is explosive enough, the engine could be run on it alone and this should clean the whole system without injury, spark plugs, valves and even the muffler, to a certain extent." This inquiry requires a very positive answer which will effectually discourage any attempt to mix oxygen with gasoline vapor in the cylinders of an automobile. In the first place, oxygen is not explosive, cannot be ignited but will support combustion. As the air contains 21 per cent. of oxygen, it must be clear even to your inquirer that it could not be used to run an automobile. If oxygen and the vapor of any hydro-carbon such as gasoline are mixed, however, the rapidity of combustion is increased in direct ratio to the percentage of oxygen added. The more rapid the combustion, the harder the explosive blow which will result. If pure oxygen and gasoline were mixed in an automobile gasoline cylinder in the right proportions, the explosive force at the time of ignition would be increased five times and in all probability, the entire automobile would be wrecked. It should be clear, therefore, that no admixture of pure oxygen with gasoline vapor in automobile cylinders should be attempted under any conditions.

In the burning out of carbon in automobile cylinders, oxygen may be used. The gasoline is shut off, the vapor is allowed to escape and the ignition of the carbon is effected by some suitable means. Once ignited, the pure oxygen blown into the carbon will rapidly burn the carbon out of the cylinder and the heat produced is not sufficient to injure the metal. The burning out of carbon cylinders in this manner is now a very generally accepted and valuable method and may be conducted without danger either to the operator or machine. Mr. Resseguie's suggestion is however, not only impracticable but hazardous.

Buy a tire pressure gauge.

Over inflation is bad for the car and its occupants; under inflation is ruinous to the tire.

Remember that after about 27 m.p.h., tire wear increases as the cube of the speed.

A LONG ROAD

To San Diego With the Smartest Girl These Men Know.

From Felix J. Koch, Ohio.—"Some trip?"

Yes, it was some trip! All the way across the continent, not as the bird flies, (which is, of course, the usual route for the motorist) but on the diagonal, the longest side of the triangle that would be formed by the drawing of a route from the northeast corner of the United States, down to the southwest corner, and then running your lines along the Atlantic seaboard and across the southern frontier. Think of it! All the way from New York to San Diego by automobile—the very first to make the journey.

Caked with dust, but grinning over their success, these first coast-to-coast motorists to arrive at the San Diego Exposition, rushed across the Puenta Cabrille on March 27th, an hour after the passage of the parade escorting Secretary of the Interior, Franklin K. Lane, on his official visit to the Exposition.

Easy Enough to See How They Feel.

Miss Margaret Gale of New York and Raoul LeMat, of Hartford, Conn., occupied the first car and the only one which came through, according to our official report, without serious mishap. Stanley James piloted the second car, but this one came on only from Chicago, where James' first car drove into a ditch and went out of commission. Three other cars had started from New York, but had been abandoned in three successive blizzards.

"It took us from January 9th to make it, and we had trouble a plenty," Miss Gale related. "I don't want the Secretary of the Interior, or any one else, to meet me until I've been to a hotel and got out from under part of this coat of dust."

"But fun? I never had so much fun in my life, and if the others are game, I'll drive back, across

Digitized by Google

country. I know we can cut that running time of two months and a half, because the blizzards in the north and the washouts in part of the southwest cost us a good many days. I'll never forget the woebegone expression of the driver we lost in Iowa. His car was buried in a snowdrift and he drove on with us to the next town, to wait for spring."

LeMat led the route from New York to Washington, then on to Pittsburgh, Cleveland, Chicago, across a corner of Iowa, and from Kansas City down along the Santa Fe trail to Phoenix.

From there he came straight to San Diego by way of the Southern National Highway. He reported the roads generally admirable, save for the seasonable difficulties, which are already practically removed in the southwest and will be removed from the northern route when spring is passed.

GASOLINE DANGERS.

The Problem of Handling and Storing to Secure Safety.

From Walter L. Wedger, chemist of the Massachusetts District Police.—As a means of furnishing power for the transportation of both passengers and merchandise, gasoline has come into general use. It is no uncommon sight to see what was only a few years ago a one-horse dump cart, containing gravel or coal, now transformed into a motor truck, with the same load increased to many times its original size, and traveling at many times its original speed.

Motor fire apparatus has become almost indispensable, and the use of gasoline is not confined to getting the apparatus to the fire, but furnishes the power to pump water after its arrival, making gasoline almost as important in the extinguishing of fires as water. I shall expect soon to see Standard Oil motor trucks filled with gasoline responding to all third-alarm fires.

Experience has proven that the underground system renders the storage of gasoline practically safe, the danger being in the handling largely. Underground tanks should be placed not less than two feet below the surface of the ground, and if within ten feet of a cellar or other open area which is below any part of the buried tank, it should be embedded in cement concrete, not less than ten inches in thickness. Such tanks should be constructed of steel plates from 3/16 to ¼ inch in thickness, and should be well covered with asphaltum varnish to resist rust.

Usually there are three pipes leading from the top of the tank—the filler pipe, the draught pipe and the vent pipe. The latter extends from the top of the tank to a point four feet above the roof of the building, and is considered necessary to conduct off the residual vapor in the tank, which is forced out during the process of filling.

In the drawing of gasoline from an underground tank by means of a pump, it is much better to use a pump that holds the gasoline in the draught pipe continuously, rather than one that allows it to run back into the tank, for in the latter case you are pumping vapor for a short time before the gasoline liquid comes.

The act of drawing gasoline from a pump and filling the tanks of cars by means of a hose or a can, through a funnel covered with chamois skin for the purpose of removing water and dirt from the gasoline, has been known to cause a number of fires by the generation of frictional electricity.

For a long time mysterious fires occurring during this process of handling gasoline have been reported to our office.

I was just as skeptical then of the fact that these fires were caused by frictional electricity as the general public is now. During the early part of last April a fire occurred at the Cambridge garage of the Metropolitan Park Commission while they were filling a car with gasoline by pouring it into a funnel through a chamois skin strainer from a five-gallon can. To make the funnel set upright on the car tank they had placed a piece of wood with a hole in it over the filler hole of the tank, thereby insulating the funnel from the metal of the tank. After a few quarts of gasoline had passed through the chamois skin, the man happened to bring the pouring can near to the metal edge of the funnel, when a spark jumped from one to the other and set fire to the gasoline vapor rising therefrom. Quick action with extinguishers saved the car. The man insisted that he saw and heard the spark, and believed he could cause it again in my presence; so, armed with a gold leaf electroscope used to show the presence of static electricity in any substance, I proceeded to make a number of tests. The officials of the Standard Oil Company, both in Boston and New York, as well as several engineers and technical men, were very much inclined to disbelieve what they termed a theory, so I invited them to be present. We imitated the conditions as they were at the time of the fire, except that we took it on the open floor of the garage. We caused the spark by simply pouring gasoline through a chamois skin covered funnel insulated from the floor, and all present saw it.

A chauffeur in a private garage at Brookline hung a five-gallon can by the bail, on the hook of a common self-measuring pump, the bail having a wooden handle, which insulated it from the metal of the pump. He had drawn about a gallon when a spark jumped from the can to the pump and set fire to the gasoline. He threw the can out of the open door and after extinguishing the fire and desiring to fill his car, he repeated the operation with the same can with the wooden handle, and it caught fire the second time.

After that the man refused to go near the pump and went to a public garage to get his car filled.

Not long after that another chauffeur in the same town proceeded to fill his car from a pump by means of a 16-foot rubber hose, to the end of which was fitted a nozzle shut off of metal. While one man was doing the pumping the other held the nozzle near the car tank, but did not bring it in actual contact. A spark, which he describes as half an inch long, jumped to the tank and set fire to the gasoline.

Several fires have occurred recently at one of the Albany oil stations, evidently caused by the generation of frictional electricity in a canvas spout used to convey gasoline to tank cars.

The canvas was covered with a coating of shellac, and the spout hung from an overhead pipe, the lower end being in or near the manhole of a tank car, but not touching the metal of the tank.

Recent tests show that the friction of gasoline passing through this spout and rubbing against the shellac coating caused the generation of between 400 and 500 volts of electricity.

HOME UNDER POWER.

Hints on How to Make Temporary Repairs Away from Home.

Roadside repairs that have been executed in the past serve to show what can be done with bolts, bars and brains. If your steering column gets bent or the steering box breaks up, must you get towed home? Oh dear, no. At any rate not if a piece of flat iron about 4 ft. long is obtainable.

This actually happened to a car after a very severe strain on the steering gear. Negotiating a hill and approaching what appeared merely an ordinary corner the driver in question was surprised to be faced with a rather severe S bend, the second turn of which was occupied by a truck. The resultant swerve smashed the steering arm coming from the box to the connecting rod and threatened an enforced and somewhat lengthy delay. This motorist happened to be possessed of some experience, however, and got home to his garage in a very creditable manner. Taking out one of the bolts securing the steering box to the chassis he attached thereto a bar of iron 4 ft. 6 ins. long, pivoting on the hole therein which had been drilled about 15 ins. from its lower end, which latter had in turn been secured to the steering connecting rod by means of some cable. The control of the front wheels was not such an easy matter as before, and was possibly reminiscent of prehistoric motoring, but proved sufficiently reliable to reach home.

Many an old car with a bevel drive and a differential stay rod fixed upon the casing has been towed or railed home on account of the latter parting company with its casing, so allowing the whole back axle casing to swivel round and the cardan shaft to drop out. This might at first appear an insuperable difficulty, but closer examination would show the problem to resolve itself into a question as to how to keep the back axle in a rigid position, secure from partially revolving. More than once this has been accomplished, with the assistance of a local blacksmith, by fitting a crossbar to the two sides of the chassis immediately over the front of the back axle and having two drop pieces fitted, one to each side of the casing. These held the latter absolutely immune from any movement, and the car was driven home, carefully, it is true, under its own power.

The same object can be accomplished by securing a stay to both the top and bottom arms of the torque rod and continuing same to the bolt holes of the axle casing. In one instance, which caused a certain amount of amusement at the repair works to which the car ultimately went, it was found that two long tire levers, with holes drilled at one end and securely lashed at the other to the stay rod, had performed this, to them, novel duty!

Whenever executing a temporary repair of this description it must always be borne in mind that the original strength has gone, not only from the affected part, but very often other parts surrounding have been weakened during the onslaught of accident; consequently a high degree of care must be exercised in driving home, especially, in the above instance, in the operation of the clutch and also the brakes, as a sudden taking up of the drive obviously tends to twist the back axle round, as also is the effect when the brakes are used. It is possible, of course, that a steep hill might prove too much for the temporary expedient employed, but, in motoring, any sort of towing assistance is objectionable, and a way out of the difficulty, no matter how bizarre, is worth trying.

Punctures, we know, belong to the category of "things which are sent to try us," and it should be seldom indeed for any experienced motorist to be caught without any spares. Suppose, however, one's stock has been exhausted by a run of bad luck and a big burst is the crowning item of a long day's misfortune! How then? Wait for a passing car, chancing whether it has the same size wheels as yours? This is where the gaiter you should carry comes in useful. Oh, you have already used it! Well, you have either to send one of your party to the nearest town or "run on the flat." But before falling back upon this alternative take the tube out. The cover may be burst, but that is no reason why the tube (almost certain to be repairable) should be ruined.

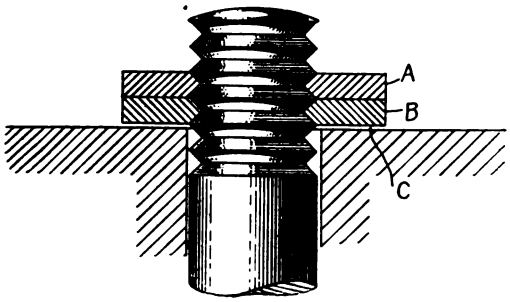
You can also, if you wish, fill the cover up with old paper, canvas, grass or anything found handy that will make the running a little softer and take some of the heavier shocks!

If, however, you have the ability and material to repair your last tube, the cover may always and easily be patched up in the following manner. Let us assume that the burst has taken the most usual form of a slit, lengthways in the tire, and about 3 ins. long. Now, first cut half a dozen strips of strong canvas about 6 ins. or 7 ins. long, and 2 ins. wide and secure three of these, with solution, diagonally over the burst. The other three must then be placed over these diagonally in the other directions. A piece of cardboard ⅛ in. thick, may then be cut to 7 ins. by 4 ins. and laid lengthwise over the canvas, the whole being bound up, very securely and right around the tire and rim, with copper wire or, better still, some common wire. A repair of this description taking half an hour to execute has carried the writer on a 17.9 h.p. car over 50 miles.

An unoffending tree bough was once pressed into service as a tow-rope! The car in question was suffering from a broken crankshaft caused, presumably, by the seizing of one of the pistons. Not having a spare crankshaft with him (which he would assuredly have put in had he had it) the owner asked a passing motorist if he could assist by towing him in to the nearest railway station, some eight or ten miles further on. Yes, he would tow, certainly, but where was the rope. No rope or chain being available it was decided to experiment with a tree bough, which was accordingly trimmed, shorn of all its beauty, and drilled at each end. Two pieces of mild steel rod of ½ in. diameter were obtained from the spares box and bent into the form of an S, hooking into the bough and respectively on to the front axle of the towed and back spring of the towing car. About 12 ft. long and 2 ins. diameter, increasing to 2½ ins. or so, this extempore "tow-rope" gave good and faithful service. A most interesting museum could be formed out of "things that brought us home."

Careful driving is an enormous factor in successful tire life.

Rusty rims are ruinous. They breed rusty beads, the direct offspring of which is rusty fabric.



An hour's run in a downpour will not cause rust to deposit. It is the day-after-day drizzle which fosters the germs of rust.

A Lock-Nut.

From N. G. Near, New York.—Very few automobilists know how to apply a lock nut, despite the simple principle. Most of them instinctively put the large nut on the inside—between the small nut and the piece being held. My sketch herewith shows how the lock nut should be applied and why. For simplicity's sake, I have made both nuts one thread thick. The action is thus better understood. First, put on nut B and screw down until it "almost touches" the piece to be held. Leave a small gap as shown at C, then put on nut A and screw down against nut B so they will both act in contrary directions. That is, the top of thread A will be in contact with the bolt and the bottom of B will be in contact.

Then turn them "both together" until they grip the piece as firmly as you wish. Of course, A and B must be screwed only "snugly" against each other, otherwise tightening will be difficult. Then, when you are sure the piece is firmly held, twist nut A

Applying a Lock Nut.

alone. B will then be forced down but little farther, due to the elasticity of metals, while the clamping action between A and B is materially increased. Where this method is followed there is but little danger of the nuts working loose and coming off. Where B is first screwed down tight and A is afterwards screwed down tigher, B becomes nothing more or less than a washer and might as well not be used at all.

Cleaning the Magneto.

From the Bosch News.—Due to its rapid evaporation, gasoline is frequently selected to wash the magneto free of external dirt or dust. Quite frequently, too, the contact-breaker and the region thereabout are given a good dousing. The need for caution is because gasoline of to-day does not evaporate as readily as it did when the refiners supplied the higher test fuel, and in consequence the surface of the washed magneto retains a film of gasoline longer than at first is suspected. Should the engine be turned over directly after cleaning the magneto, a spark from the contact-breaker would set fire to the film of gasoline which covers the magneto and what would result is hard to say—maybe little, maybe much.

If the wires to the spark-plugs have been removed, there is an additional possibility of a conflagration, for gasoline may have been forced into the chamber of the external spark-gap, and should any action cause the magneto's armature to be rotated, a spark would pass across the spark-gap and light the liquid.

There is no danger of all this occurring, if the magneto is wiped dry, gasoline used sparingly and the magneto or car not put in immediate operation. Just common horse sense saves a lot of trouble in life.

Another point—should the magneto be totally taken apart, it is not entirely wise to wash all parts in gasoline and then assemble. It would be preferable to wash all parts thoroughly in gasoline and then in clean kerosene oil, for when steel parts are washed in gasoline, they become absolutely dry as soon as the gasoline evaporates, which causes these parts to be more susceptible to rust. Ball bearings in particular are sufferers, so that when these are replaced they should be given a thorough covering of light oil—not soaked in it, but covered with a film. It not only lubricates but protects.

The armature can be washed in gasoline, but it is not a good practice to permit it to soak, as the armature covering may be softened and a possibility exists of damaging the condenser also.

One point that cannot be sufficiently emphasized is the warning that only those who are thoroughly conversant with magnetos should attempt to dismantle them. So much depends upon an ignition system that when it requires cleaning or adjusting, it is best to place it in the hands of real experts, rather than take the responsibility yourself. This, of course, applies to complete disassembling and important internal adjustments not covered in the regular instruction books.

Remember, a blacksmith may be able to make an excellent wagon axle, but he hardly could be expected to repair a split second stop watch.

Starting and Stopping.

"In starting or stopping a car, when the power is applied or the brakes used, there is a tendency of the rear axle to turn with the wheels," declares Elwood Haynes, pioneer auto builder. "As was customary with the older designers, instead of using parts already at hand, an additional part was added to the car in the form of a long heavy bar. This bar extended from the axle to the frame and prevented the turning of the axle. In the later designs, the Hotchkiss drive is used. This term is applied to the driving system where the rear springs take both the drive and torque of the rear axle. In other words there is no torque bar extending between the rear axle and the frame of the car. The two rear springs keep the axle from turning. Greater simplicity and flexibility are obtained. The axle is subjected to no sudden shock because the construction is slightly yielding.

"A baseball catcher extends his hands out as far as possible to catch the ball and then allows his hands to come back to stop the ball gradually. It would be too much of a shock to stop the ball without moving the hands. In other words his hands yield to absorb the shock the same as the springs take up the jerks on the axle.

"An attempt is made in the torque bar construction to obtain a yielding action by carrying the forward end between two short coil springs, but the rear axle must bear greater jerks and shocks than can be given it with the Hotchkiss drive system which consists of nothing more than two long flexible arms in place of the one rigid bar."

Never steer suddenly except, of course, in case of necessity.

THE JITNEY SITUATION.

How the present invasion of passenger traffic in cities and towns by the jitney automobile service is to end it is difficult to foresee. Take one single town as an illustration, although quite likely other more forcible instances might be made concerning the havoc this service is creating in the electric street railway business.

Street railway passenger traffic in Winnipeg, Canada, has decreased to such an extent since the advent of the jitneys that the Winnipeg Electric Railway Co. has been forced to adopt new measures to cope with the situation. This will involve a reduction in the number of cars on the various routes, a reorganization of routes, and a probable reduction in staff.

"I may say that the proposed reduction in service is not at all in line with the decrease in traffic," says the company's manager in a letter to the civic board of control. "If we were to merely put in such service as to take care of the present traffic, it would mean a much greater reduction. I also want to inform the board that if traffic continues to decrease, further changes in the service will have to be made to meet the conditions." The company does not mention the jitneys in its letter, but undoubtedly they are a factor. According to city officials, there are 572 jitneys operating on the Winnipeg streets, 428 of which have jitney licenses.

But the end is not yet. The street railway traffic has developed slowly until everything is conducted along strictly economical business lines. Although this business has proven profitable, yet attempts to reduce fares lower than five cents have proved disastrous. With liberal franchises, and tracks and cars constructed specially with a view to the lowest possible cost for the service, it would scarcely seem that an ordinary automobile could do the work for the same price.

It can be readily understood that in the establishing of a jitney service the receipts of a single day or a week may seem encouraging for a profitable business. But how will it be when the year rolls round, with good weather and bad, and possibly in winter a period of deep snow? And how long will an automobile last when put to the severe jitney service? The matter of gasoline and oil are but a small fraction of the cost of up-keep. Tire wear, paint and varnish, and general repair will naturally be heavy from such continuous strenuous use. The jitney service is yet in its infancy. Indeed, in some instances jitney owners have already found that 5 cents is too low and the fare has been raised to 10 cents. In St. Louis a study of up-keep costs has convinced the owners that carrying passengers a distance of 4 miles for 5 cents each is a losing venture. It costs 7¼ cents a mile or 29 cents for the 4 miles according to estimates given by the manager of one of the jitney lines. It would be necessary to carry six passengers on each trip to cover the operating cost but this is seldom possible, because there are hours during the day when trips are made with three and four passengers, and during the rush hours of the morning return trips from downtown are often without a passenger.

The automobile will ultimately be a greater menace to the general railway business than to the street railways. An important essential to profit in the jitney service is speed, and speed is not always possible in congested districts. On the other hand, between cities and towns, where the passenger traffic is heavy and where rapid speed may be made, jitney service will prove decidedly uncomfortable competitors to the railroads.

LAW VIOLATORS.

One of the most pernicious tendencies of everyday life is a noticeable lack of respect for the law. It exists more or less among all classes, but is most apparent where the culprit can "see no harm in it." Or possibly it might be more accurate to say where the culprit pretends to see no harm in it.

Take the case of violations of the speed law, for illustration. We have heard individuals refer in even a boastful way of having done it. The other day a man came into a garage where his motorcycle was stored, took out his watch, and said: "Eighteen miles in 25 minutes; well, that is pretty good time, but I wanted to get in before it began to rain." Then the individual chuckled, as he related how he had avoided arrest on other occasions when he had exceeded the speed limit.

Of course, the person referred to was rebuked as he well deserved, and his qualities of mind and heart are plainly indicated by the remark quoted. But there are a good many individuals of this sort—far more than might be expected—and they are almost wholly responsible for whatever ill-feeling exists for both automobiles and motorcycles among those who do not use them. And the motorcycle is more unpopular to-day than the automobiles, and de-

Digitized by Google

servedly so, for it is largely used by those who have an untramelled ambition to "burn up time and space."

It is admitted that this class of law-defiers is not a large one. But like other evil things, they often put a stigma upon the whole. Of course, there is but one thing that can be done to mitigate the evil. Ignorant and unscrupulous human nature can't be made over; it requires generation after generation of example and precept to do that. But even this sort of human nature can be inspired with a wholesome fear. The law against such offenders may be made more severe, and it may be more severely or strictly enforced. There is absolutely no other remedy. Articles of this sort may be written by the press of the country until the crack of doom and they will have very little effect. What is needed is more severe punishment.

Then a duty is incumbent upon lawful users of automobiles and motorcycles. It is plainly their duty to rebuke such instances of lawlessness in the plainest and most forceful terms wherever and whenever it is manifest, just as was done in the case referred to. Such a course is unpleasant, it is true, but if duty were invariably pleasant it would seldom be violated.

A GOOD LAW.

The new automobile law of New Jersey is a good one. It virtually places users of the public highways on an equal footing where they belong. No longer are automobiles to be made the "goat" in the sharing of responsibilities, or the favorites in the sharing of rights. This law defines the rights and duties of every user of the highways, from the pedestrian up to the driver of a high-powered automobile. Moreover, these rights and responsibilities are set forth in minute detail, so that they are easily understood, and if they are properly enforced the number of accidents will be greatly reduced.

Under this new law the word "vehicle" includes not only automobiles, but horseback riders or horses that are led, and everything on wheels or runners, except street railway cars and baby carriages. The word "driver" covers the rider or driver of a horse, of a bicycle, or a motorcycle, an automobile or a street car. Horses, mules and all other domestic animals used as draft animals, or beasts of burden, are likewise placed in the same category.

We have not the space to publish this law in full, but those in other states who are interested in having a sensible automobile law may well send to the Secretary of the State of New Jersey and secure a copy of it. One provision will be especially gratifying, and as far as we know it is somewhat unique, namely: It is unlawful for bicycle riders or roller skaters to attach themselves to vehicles of any kind or trolley cars. Another provision cannot be considered of quite as much merit. It provides that no vehicle shall travel at a greater speed than six miles an hour when passing or approaching a schoolhouse, providing signs are placed on the highway so that those approaching may be aware of the location of the schoolhouse.

The law, however, in its general features is so sensible and just that one can't but wish the same law existed in all the states.

USED CARS "ON TIME."

A Method Which Has Proved Successful for Seller and Purchaser.

From G. D. Crain, Jr., Kentucky.—Although some automobile dealers are taking paper in partial settlement for new cars, it is probable that the bulk of the business on machines fresh from the factory is still on a cash basis. When it comes to second-hand cars, however, an entirely different method has been developed.

Instead of having to plank down the hard cash for his car, the purchaser of a used machine can often get terms which remind one of those offered by the piano and talking-machine dealers. They are not exactly "a dollar down and a dollar a week," but concerns which have specialized in the used car business are making it very convenient for those who want to buy.

One concern in a Middle Western city, which is said to have the largest used car business in that part of the country, advertises a method whereby $50 will get any car on its list. It does not, however, deliver the car on an initial payment of this amount, but simply reserves it for the purchaser, who gets the machine after 25 per cent. of the purchase price has been turned in.

This really amounts merely to a savings bank arrangement, wherein the automobile concern is the banker; and, to carry out the idea still further, the dealer referred to pays 4 per cent. interest on the deposit which is made prior to actual delivery of the car, so that the purchaser can hardly lose.

In addition to attracting the attention and getting the business of people who might assume that purchasing an automobile is an impossibility for them, since the $50 limit undoubtedly brings an immense number into the field who would not be able to consider a larger immediate outlay, the same company makes a special play for "time" business of larger amounts, offering cars up to $700 values on the monthly payment plan.

Showing that it believes that most people are honest, and that the credit risk is not excessive, this company has been advertising aggressively in the territory nearby, and has sold a good many cars on the instalment plan to people living several hundred miles away from its community. Apparently it has experienced little trouble in making collections, and feels that the "time" system is just as logical in the sale of autos as furniture, pianos and other goods which have been sold this way for many years.

Such a business suggests, of course, that the dealer must know what he is selling, and be willing to stand back of it after it gets out of his hands. The concern which is getting spot cash for a second-hand car can be fairly independent about it after delivery. On the other hand, when the customer has merely paid in part of the purchase price, it is evident that he must continue to be satisfied with his car, or there is risk of its being thrown back on the hands of the automobile company.

In fact, this is the point which has always seemed to present an insuperable objection to the system of selling on the instalment plan. So many things can happen to an automobile. It can burn up, get out of condition, have a collision, or what not, and any of them can make the machine rather unde-

Digitized by Google

sirable property to the owner. But the instalment concern referred to does not believe that the chances favor anything of the sort. For one thing, it has the car insured, with the policy in its possession, until it is paid for, so that the possibility of its destruction by fire or other casualty is taken care of. And as for the machine giving service, it guarantees it for one year, and its system of payments provide for it being paid for within that time.

A twelve months' period is usually the limit covered by the guarantee on a new car, although many dealers think they are stretching it a point when they guarantee a used car for ninety days. The instalment plan makes the interest of the dealer just as keen ten months after the sale as three, however, and he would probably have to make some sort of adjustment satisfactory to the customer if anything went wrong before the machine was paid for, so that the guarantee is really making a talking-point, for selling purposes. But the dealer makes good by giving every car a thorough overhauling, which amounts to rebuilding, before he puts it out for resale.

This was what was meant by saying that the dealer, under the instalment system, must know what he is selling. He simply can't afford to put out a car which is likely not to give service, because of the certainty of its coming back on him. In such a case the payments already collected would seldom be sufficient compensation, considering the cost of putting the automobile back into presentable shape and selling it again.

Contrast this plan with that which has been in use in some cities, of conducting public auctions for the purpose of relieving the glut of used cars, which develop to a greater degree late in the winter than at any other time. People who have lost their zeal for motoring during the cold weather; those who have simply "needed the money," and those who have been persuaded, by longer allowances than are made during the active season, to trade in their old cars on new ones, have all contributed to the supply, while weather conditions have held down the demand. Hence the first few months of the year usually see an excess of old automobiles that makes one believe, until he actually begins to look around, that he can get anything he likes for any amount he may care to pay.

Under the auction system nothing whatever is done to the car. The buyer looks it over, like a horse at a fair, and forms his own judgment about the value of the car, and the amount of money that would be needed to put it in first-rate condition. No guarantee of quality or satisfaction is made, and it is a case of the buyers pitting their shrewdness against each other, and picking winners from among the cars of all descriptions which may have been offered.

In one city there have been, during the past few months, three regular "auction blocks" where weekly sales of used cars have been held. Some of the wrecks that have been unearthed and put up might have furnished good material for the Smithsonian Institute, but as a matter of fact about the only interested persons were junk dealers. One old car, apparently about ten years old, had to be hauled to the auction. Many of its parts were missing. Its running-boards were in a state of collapse, the steering gear had fallen down upon the front seat, the top had several broken ribs, and the engine was a mass of rust. It was sold for a few dollars and broken up for junk, of course.

On the other hand, some fair-looking cars are often put up for auction, and now and then real bargains have been secured. Many business men who want to buy passenger cars of good make, but obsolete body design, with the idea of mounting a delivery body on the chassis, have found the auctions a good place to locate autos of the type desired, and possibly have secured better values than they might have got otherwise. Yet the man who was deceived by a fresh coat of paint and a pair of new foredoors, into buying a car several years old, under the impression it was a late model had no recourse, and none but himself to blame, when he discovered his error later on.

Rebuilding, guaranteeing and selling on time, as against putting up for sale at public auction without investing anything in work, is the more conservative, but in the end the more satisfactory method. Better prices can be realized, greater satisfaction can be assured the purchaser, and more real automobile enthusiasts created. As a matter of fact, many a man who has feared to buy a car, because of the high cost of maintenance about which he has heard, has been attracted by a low-priced used car into entering the ranks of the motorists. Having found that he could run it and accumulate a fair mileage without bankruptcy, he has gradually improved the character of his automobile until he gets to the top of the heap.

And from the standpoint of the dealer with gasoline, oil, tires and sundries to sell, a used car owner looks just as good as the man who has invested in an eight-cylinder made in 1915.

SOMETHING ABOUT DRILLS.

Useful Information About the Various Kinds of Drills for Lathe Work.

For drilling in a lathe, the drill known as a twist drill is employed for two reasons. First, it has a capacity of drilling straight and true, and second, because the twisted flutes afford excellent and free egress to the cutting and permit of the hole being drilled without removing the drill to get the chips out. There are instances where the straight flute is employed and has advantages over the twist drill but this will be found only in such metals as brass and copper, and in this case they require special grinding, as will be taken up later.

A number of different shanks are employed in different machines but the most common in the small drill is the parallel or the straight shank, sometimes called "jobber's drills." In the larger drill the taper shank, known as the Morse taper, is employed and is held in position by being forced into a taper to fit the drill shank. The small straight shank drills are held by small chucks, as the taper shank would make them more expensive and in many instances quite unsatisfactory.

An ordinary twist drill has three cutting edges, as shown in Fig. 1, at A, B, C. The ordinary drill cannot be made as keen as is desirable for rapid and clean cutting, and therefore, necessitates an increase in speed to overcome this handicap as compared to other tools employed for cutting metals.

The circumference between flutes, known as the

Digitized by Google

"land" of the drill, is obtained by grinding from the cutting edge, B, to the back of the flute, C. This is backed off to give clearance, as is shown by the dotted line, D. Consequently the drill has its full diameter at only the two points, as shown in the drawing B to E, Fig. 1. The object of grinding the drill in this fashion is to prevent it seizing from heat or dragging against the walls of the hole and

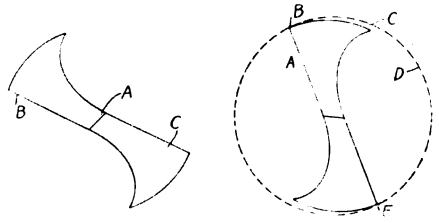

Fig. 1.

cause it to require an unnecessary amount of energy to turn it. In case the "land" of a drill is worn off and the drill be perfect in every other particular, it will be found practically worthless for drilling any depth. Most twist drills have two flutes only. However, three and even more have been made, but owing to the more delicate, complicated operation in grinding, its advantages are counterbalanced to such an extent that it is not considered practical. Therefore, the keenness and durability of the cutting edge of a drill are governed by the amount of clearance given by the grinding of the cutting edge to correspond to the twist of the flute.

The angle of the front face of a twist drill varies at every point in the entire diameter of the drill, being governed by the spirality of the groove or flute. The sooner we acquaint ourselves with these peculiarities found in standard drills the sooner we will get better results with less efforts.

In Fig. 2 we have a drill, B, ground exactly true and the "land" of the drill bears exactly the same

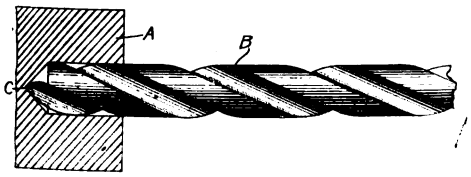

Fig. 2.

all around the walls of the hole. A drill ground in this manner will wear until the flutes are ground entirely away and cut clean, straight holes. On the other hand, if one of the cutting edges is a trifle longer than the other the drill will cut a hole larger than the drill and the result is the drill will be dulled very rapidly on the side doing the cutting. If the hole drilled is of any depth, it will be smaller the deeper it is drilled, leaving it an irregular taper with rough walls. The point, C, will be ground around in something of an eccentric motion in the block, A, and the "land" of the drill on the one side will be destroyed, rendering the drill useless for accurate work.

Then again, we may take a drill ground accurate and increase the feed without, however, increasing the speed accordingly, and get results much resembling the drill ground out of true. If we take a drill with one cutting edge ground longer than the other and the two cutting edges at entirely different angles to the angle of the axis of the drill, we will drill a hole with crooked rough walls, varying in size from top to bottom. Where drills are employed for any amount of drilling and where it should be done accurately, a machine for grinding them should be employed, as the cost will be saved in drills and time in a very short time. It seems to me if some one would invent a simple device which could be attached to the ordinary grinder it would find a ready market.

When drills are ground by hand, a protector, as shown in Fig. 3, should be employed. The length of the cutting edge, C, can be measured by the indicator, D, on the scale of the protector. The flutes of the drill can be kept to the scale of the protector at A, thus giving a very satisfactory grind with a little practice. Care should be taken in grinding drills to not reduce the diameter of the drill by grinding into the "land" of the drill.

At A, in Fig. 4, we have a drill known as a straight flute. It is employed for drilling certain metal where it has quite an advantage over the twist drill. These drills work especially well in brass and will work at a higher speed, without having a tendency to gouge than the twist drill. Then we have again

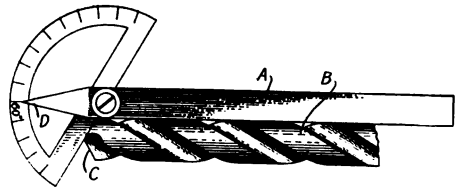

Fig. 3.

at B, in Fig. 5, a drill used for drilling wood and driven by a machine. This drill is made with a conical point, E, which serves to steady it. Then it has two spurs, D, which cut the wood before it is removed by the bit, permitting of a clean wall instead of a rough torn one, as would result in case the ordinary drill were used for this purpose. Flute C, removes cuttings.

For drilling cylinder work a block, as shown at B, in Fig. 5, is employed to rest the work against. The shaft or pipe rests in the lowest part of the block at A, and the forks prevent it turning or moving sidewise while being drilled. C represents a similar block used for the same purpose. Then again we have at D a block of similar construction except the grooves are different widths which come in good play for holding shafts of different sizes

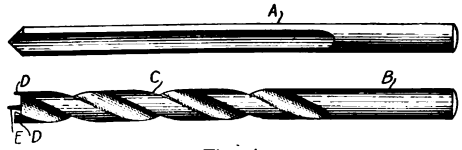

Fig. 4.

from the smallest up to the capacity of the block. A number of these blocks of different sizes should be added to the equipment of every drill press as they will save their price in drills in a very short time. When a shaft drilled part way through turns under the drill, it will invariably break the drill. In case the drilling is done in the lathe the cross should be fitted to a taper spindle which in turn fits the tail stock of the lathe.

We have in Fig. 6 another type of drill or boring

Digitized by Google

bar employed for enlarging holes in pulleys and the like. This tool can be used either by hand or in a lathe or drill press. The body of the drill, A, should be the size of the existing hole in the pulley, especially at the end, E. The dotted line, F, represents the hole to be enlarged. A cutter is made and placed in the body of the shaft, A, as shown at C, and held in position by the sunken screw, D. The end of the shaft, B, can be fitted to the drill chuck or squared for a tap wrench and turned by hand. The cutter, C, can be adjusted to make the entire cut at a single operation, unless it is an unusually large one.

A number of these tools should be on hand at all

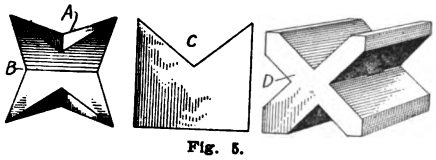

Fig. 5.

times as many pulleys are brought to the shop to be bored that are larger than the swing of the lather or the drill press. Or a simple one can be made with a number of different sized collars to slip over the lower end at E, giving the necessary sizes for a large range of drilling.

In drilling, the lubrication of the drill should be considered as one of much importance, especially in tough stock. In cast iron it is not necessary to lubricate the drill unless in extreme cases. Steel should be lubricated with a good lard oil, and the speed of the drill should be looked to as well as the feed, as each holds relation to the other. Drilling brass and copper differ quite a little from drilling iron and steel, and one should see that the drill will

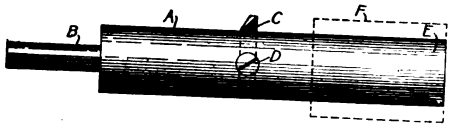

Fig. 6.

vary quite a little. The very small drills will give satisfactory results at a high speed while the large ones should be run quite slow and not feed too fast.

Cross drilling requires skill in judging of speed and feed, as when the drill breaks through if the speed is slow and the feed light, a tendency will be for the drill to catch and break.

Can Anyone Tell Him?

From George G. Keen.—Does anyone of your readers own or know anything about the Winton four-cylinder car of 1905, Model B? Cylinders are horizontal (not upright) and are placed under the driver's feet. Gasoline tank under hood. Transmission gears do not slide but remain always in mesh. There is a clutch for each speed—for low, high and reverse. Also there is a brake on the high speed shaft. Intake valves of engine are automatic, opening and closing without tappets. I am overhauling such a machine and would like to know your opinion or your readers' of such a machine.

Tension rods usually break where the threads have weakened the rod by cutting down the working diameter. The rods should be made larger at the threaded ends to allow for this weakening.

SPRING CLEANING.

A Few Things It Is Well to Do for the Good of the Car.

Although all cars do not require overhauling once a year, all require more or less attention in the spring. This ought to include a thorough cleaning of all the mud, grease and rust from the running gear; the removal of all the oil and grease from the interior of the motor, gearset, universals, axles and wheels, followed by a flushing out with kerosene; refilling all these with grease or oil; and removal of carbon from the cylinders. If the carbon is not caked too hard it can be removed by pouring a half-cupful of kerosene in each cylinder, then turn the engine over a few times and let it stand over night. Run the engine a few minutes in the morning till the black smoke disappears. If the carbon will not yield to the kerosene or some of the patent carbon removers, the services of a repairman with a removing outfit better be engaged, unless you want the tedious job of scrapng.

By the time you have gotten this far in the work you will have located a great many more grease cups and oil holes than you ever suspected the car possessed. These will all need refilling. Some of those that will need attention are the fan, starting crank or electric cranker and generator, pushrods, magneto, control rods from the steering wheel, the clutch and brake operating mechanism, axle bearings, steering gear and connections and the grease cups on the motor, clutch, universal joints and spring shackles and brake connections.

Then look over the electric wiring for ignition, lighting and cranking. Look for signs of wear in the insulation. It often is found that where wire gets a slight constant rubbing the insulation wears through, inviting a short circuit and damage to the battery. The application of a little insulating tape often will save much trouble in this respect.

Take the spark plugs out and clean them. They are likely to be fouled with carbon. Should there have been any gasoline left in a car which has been standing for some time, or should the car have been in service for a season without inspection, it is better to drain out the fuel tank by disconnecting the feed pipe at the bottom of the tank and at the carburetor. If the gasoline is of recent purchase, save it; if the car has been standing many weeks, there will be little left to throw away, and that not much good as gas-engine fuel. Take off the filler cap so the gasoline will drain as fast as possible to carry with it whatever dirt may be collected in the tank. Clean out the strainer, if there is one.

Drain out the carburetor, and then attach one end of the tire pump hose to the gasoline feed pipe you have removed and force air through it for a few seconds. This will remove the sediment that has collected in the line and which later might lodge in the carburetor nozzle with disastrous results. It is a very good plan if the car has a cone clutch to give it a good soaking with neatsfoot oil. This can be done without removing the clutch by wedging a board between the pedal and the front seat so that it holds the clutch out of engagement. Then pour the oil from a fine-nozzled can upon the top of the leather so that it will run all over the face of the clutch. Leave it disengaged for several hours to allow the oil to soak in. With a disk style of clutch

Digitized by Google

in which the disks run in oil, it is only necessary to drain out the old oil, flush the case out thoroughly with kerosene and then fill up with fresh oil. If you put in light oil in the fall, go back to the heavier grade in preparation for the warm weather. Gearset and differential should be cleaned out and new grease put in.

Make sure that the bearings are not worn and the adjustments set up properly. When the gearset housing is opened and empty, take hold of the shafts and try to work them up and down, to see if there is lost motion in the bearings. If annular bearings or non-adjustable plain bearings are used, it hardly would be advisable to try to take up any lost motion, except where it is marked enough to cause possible trouble before the next overhauling. In the latter case it is a job for the service station or repairman. The same is true of the axle shafts when the differential housing is open, only this is perhaps the more important. The meshing of the bevel pinion and gear should be looked to, because usually after a season's use this is in need of adjustment. More important still is the inspection for wear and adjustment of the steering gear, because trouble at this point is most likely to be the cause of an accident.

Screw out the grease cup on the steering gear case and squirt a few gunfuls of grease into it. If there is excessive play in the steering wheel, see whether the lost motion is between the wheel and the steering arm or between the arm and the road wheel. There probably is a simple adjustment for wear between the steering wheel and the arm. If there is none, it is another job for the repairman. Likewise, if the play is between the arm and the road wheel, there may be an easy adjustment, if not, let a mechanic do it. If the wheels look at all out of alignment or have a tendency to wabble, the best plan is to get the service station or a repairman at them right away, because they will keep getting worse instead of better and every mile means increased tire wear.

If the tires have been running all winter, they have had the hardest service of any part of the machine. If the tires have not been off in several months, take them off now, take out the tubes—and do it carefully or they will be ripped where they stuck to the casing. Test the tubes for leaks, and go over the casings for cuts and blisters. Cuts can be filled with some of the compounds for the purpose if they are not too bad; bad ones will need vulcanizing; otherwise, some rainy day you will be hung up in the mud with a blowout.

Brakes need a complete going over for worn connections and a liberal application of grease wherever possible.

While too lean a mixture is the usual cause of "popping back," it must not be forgotten that any defect in the intake manifold, either original or acquired, may cause only one cylinder to get too lean mixture, and cause "popping back" when the average mixture is right.

Owing to the fact that the float in the carburetor is violently agitated when the car is traveling over rough roads, the gasoline level is practically raised, and more gasoline is fed to the engine than is needed.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Misjudged Speed of Street Car.—One man and woman are dead, their daughter frightfully injured and another man badly hurt as the result of an accident at Kalamazoo, Mich. It appears that the owner and driver of the car in which these people were riding turned his machine in front of a street car. The automobile was hit squarely and its occupants hurled against a telephone pole. The woman died on her way to the hospital and the man underwent an operation on his skull but did not recover and the girl's condition is very serious but there are hopes of her recovery.

Steering Gear Snapped.—At Richmond, Cal., a young man sustained a crushed chest, internal injuries and possibly a fractured skull as the result of an accident which occurred when his steering gear snapped and he lost control of his machine. The car overturned and pinioned him beneath.

Stood Up in Car.—At Spencer, Ia., a little girl stood up in a car in which she was riding with her father. She suddenly fell back out of the car, breaking one of her legs in two places and the other in one. The child seems to be rather unfortunate as but two weeks previous to the time of this accident she had broken both her arms.

Due to Absolute Carelessness.—An accident in which one man was killed at Kentland, Ind., is due to absolute careless and reckless driving. The driver of the car in which the man was killed attempted to pass a car ahead where there is a deep ditch and very little room. It seems that the drivers had been racing and it was simply the senseless desire to get ahead which caused the accident. The car ran into the ditch into a corn field and overturned, killing one and injuring the other occupants of the car.

Drove Car Through Closed Gates.—One woman was instantly killed and three other persons injured when the driver drove the car through the closed gates at a railroad crossing, directly in front of the switch engine. It is stated that the woman's head was completely severed from her body.

Car Skidded.—A man was killed at Cincinnati, O., when the car which he was driving skidded off the side of the road. The car was overturned, pinning the man beneath and breaking his neck.

Lost Control of Car.—At Ramsey, Ill., a woman was instantly killed when her husband who was driving lost control of the car in going down a hill. The machine plunged over a ledge 15 feet below, landing upside down.

Clutching the Wheel.—At New York City, a car was seen coasting down the roadway and finally hit the tail end of a wagon and stopped. The man at the wheel was found to be unconscious with both hands clutching the wheel. He was taken to the hospital and died shortly after. It is believed he was stricken with apoplexy just after he had shut off his engine to coast down the hill.

Stalled on Railroad Crossing.—In saving the lives of his wife and three other persons, at Gary, Ind., when the automobile in which they were riding became stalled on the tracks, a man was struck by

Digitized by Google

a locomotive and badly mutilated, the top of his head being severed. No gates guarded the crossing, although there is a warning bell and an arc light and the tracks can be seen in both directions. It is thought that the party imagined they could clear the tracks when the engine suddenly stalled and the man pushed the car to safety but lost his life.

Plunges Into a River.—Four persons were killed near Seattle, Wash., when the car in which the party were riding ran off a bridge and fell thirty feet below into a river. The car is said to have skidded as it approached the bridge.

Attempted to Save Her Hat.—A woman at Dallas, Tex., may lose her life because of an attempt to save her spring hat. The young woman's hat blew off when she alighted from a street car and when she attempted to save it an automobile knocked her down. Physicians are doubtful of her recovery and the driver of the car is held on a charge of reckless driving.

Falls Asleep at Wheel.—A man was rudely awakened from a nap at Brentwood, Mo., when his car plunged into a hole beside the road. It is said that the machine was badly damaged but the man escaped with slight injuries.

Grade Crossing Accident.—Two men were instantly killed at a railroad crossing in Sherwood, O., when the car in which they were riding was struck by a locomotive and completely demolished. Both men were mangled almost beyond recognition and their bodies carried two or three blocks east of the crossing. It is stated that the car was enclosed and the curtains were on, which probably prevented them from hearing and seeing the train. It was also a dark and stormy night which no doubt made the situation worse.

Dashed Around a Street Car.—A man was probably fatally injured at Lima, Ohio, when in passing a street car which had stopped, another car dashed around in front of the car and crashed into his machine, inflicting injuries from which he will probably die.

Disregarded Signal.—Three young men were killed and another man will probably die as the result of an accident at Lincoln Highway, New Jersey. The young men were returning from an alumni dinner and were speeding along a dark road. As they approached a drawbridge the gateman signaled to the automobile with a red lantern but the car tore through the iron gates and made a fifty foot leap into the river. Witnesses state that the car was going at the rate of fifty miles an hour.

Drove Car Into River.—Near Avoca, Ia., a woman was instantly killed, her neck and back being broken and she was buried in mud and water. The man accompanying the woman, who was also the driver of the car, sustained severe bruises and shock.

Tail Lights Out.—A young woman and her fiance were killed at Chicago, when the engine stalled on the car tracks. The motorman states that the tail lights were out and he was unable to see the machine until too late. The owner and driver of the car was also knocked unconscious and thrown from his car.

Caused by a Copperhead.—In New Jersey one Sunday a man took his family out for a drive. He stopped by the side of the road, at an incline, while the party went over into the field to pick flowers. When they returned they found a copperhead snake had taken possession of one of the seats of the car. Naturally the man was somewhat agitated, but he procured a stick and made a desperate effort to kill the snake. In doing so the car started down the hill and was soon overturned and wrecked. It is hardly necessary to state that the snake escaped. Where there is an incline together with possible copperheads it is well to put the brake on the car.

RULES FOR BEGINNERS.

Suggestions Which Are Usually Known But Are Not Always Borne in Mind.

From J. N. Bagley, Nebraska.—There is hardly a town of any size in this great United States where cars are not sold by some one. Many of these agents know very little about a car, and consequently the person buying it does not receive the instruction necessary to properly drive or care for it. This may result in serious accidents. A car should never be turned over to a new man until he thoroughly understands it. In such a case the buyer should call upon some one having the particular type of car and get his assistance, for almost anyone will be glad to help a new man along and give such information as he needs. Many times the owner of a car is better able to instruct the beginner than the agent.

To Start the Motor.

To start the car, one should make sure that the ignition switch is in the "on" position, and that the gear shifting lever is in neutral position, so that when the motor starts the car will not move until the operator is ready for it. The spark lever should be retarded if cranking on the batteries, to eliminate the danger of a kick back doing injury to the person when cranking. If cranked on the magneto the lever should be advanced to about two-thirds running position, as the spark is a trifle slower when started on the magneto. The throttle lever should be in a retard position, but advanced just enough to allow of a small amount of mixture to be taken from the carburetor, as in nearly every case the motor will start on a light throttle better than a heavy, and besides when it does start if the throttle is wide open, before it can be closed the motor will race with a howl before it can be closed which is injurious. In cranking the motor it is not a good plan to go down on the crank, but to place the crank in position and lift up, keeping the thumb on the same side of the crank as the fingers, for in case of a kick back the crank will be jerked from the hands without doing any injury to the person doing the cranking. At first the new motor will crank a little hard, as all bearings are set up tight to insure long life. The cranking of a motor is not an art, but a simple "knack" and one will realize this better as they do the job a few times. As soon as the motor is started, move the switch from the battery to the magneto and work the throttle before attempting to move the car.

Starting the Car.

We will assume that the car is ready to start and the motor is running along slowly. Press the clutch pedal, slightly releasing the clutch, and place the gear shift lever in position for low gear. Open the throttle a trifle to speed up sufficiently so that the load will not kill it. Now gradually let the clutch in until the car begins to move. Then remove the

Digitized by Google

clutch the second time and make the change of gear from low to intermediate and let the clutch back rather quickly before the car slows down too much. As soon as the car is moving well in intermediate we are ready to take the high gear. This is done in a like manner, but quickly allowing the engine to take the load with the car moving with as near the same speed as possible as when it was intermediate. In case the speed is required to be advanced, do it gradually and not abruptly. When the power is applied with a jerk it causes an unnecessary strain on all driving members.

Bear in mind at all times that the ability to bring the car quickly to a stop is occasionally of greater importance than to start or drive it. To stop quickly, release the clutch, throttle the motor and press the service brake down, applying the pressure gradually. All this time the clutch pedal must be held in the released position. As soon as the car comes to a stop the lever can be placed in a neutral position and the clutch released.

In stopping the car, pull the emergency brake lever back. This will lock the rear wheels and prevent the car moving if the ground is sloping. To stop the motor after stopping the car, throw the switch on the dash and at the same time open the throttle about half-way, allowing a rich mixture to be drawn into the combustion chamber of the motor and the next starting will be quite a little easier. An emergency stop may be made with both the service and emergency brake, but this should be done only in severe cases as it is apt to slide the wheels and do injury to the tread of the tires.

Changing Speeds.

Quite often the driver of a car is compelled to accommodate the progress of the car to the movement of the crowded traffic, or to climb hills or force the car through stretches of sand, mud and clay, and it becomes necessary to change from a higher speed to a lower one. The time at which the change should be made must be determined only by experience, and nothing but driving will make an expert in this particular. It is always better to climb a hill slowly and be sure of the completion of the climb, rather than to risk having to pull back through the gears, especially for the beginner. When changing to a lower speed it is necessary to advance the spark. Changing from a lower speed to a higher, requires that after the speed is disengaged the motor be slowed down before engaging the next higher. One should bear in mind continually that it is not necessary to force the gears into position but that when done properly they will drop in with very little effort and almost noiselessly.

Accelerator Lever.

Having gone thus far, we find that besides feeding the motor with fuel by hand we have another device generally for the right foot, and this is known as an "accelerator." Some of them are supposed to move up and down while some of them move sidewise, but the function of either is the same, as the hand lever and the accelerator are inter-locked. The accelerator gives greater freedom to the operator's hands and is an occasional relief and a rest from the throttles. When the car is on a level stretch and is running at a certain speed, the throttle can be placed in position and the foot rested as the foot will tire of a continuous use, especially if the speed requires it to be held in one position for miles.

The Muffler Cut-Out.

Ordinarily the gas passes directly from the engine to the muffler via the exhaust pipe made to secure both, but in some cases a cut-out valve is placed in the line to allow of the gas passing directly through the valve to the open, without going through the muffler. It has been found that muffler designs cannot be made so that a certain amount of back pressure will not occur. Consequently, the opening of the muffler on a hard pull will give a little additional power as well as keep the engine a trifle cooler. It also serves a good purpose in telling when the cylinders are all working perfect as an experienced person can locate many troubles by the sound of the exhaust under different conditions. While the muffler cut-out has its advantages its indiscriminate use, as in traveling through the country at night, etc., is apt to be a nuisance to others.

Some Road Rules.

Before venturing upon the highway, the new beginner should acquaint himself with certain road rules. As a rule the motorists are a law-abiding class, and none but the reckless will refuse or neglect to pay obedience to the rules established by law governing such things. When meeting another vehicle coming from the opposite direction both should keep to the right, each turning to one side of the center of the road. If the coming vehicle be a heavily loaded wagon, it is as a matter of courtesy, proper to give the entire road if possible. In passing slower machines or vehicles going in the same direction, it is proper to go around to the left. When traveling very slow and a machine comes up from behind, give the road, allowing the vehicle to pass. Of course, there are other laws than these, but as almost every person knows the laws governing the public highways, it is almost useless to dwell longer on the subject, but I would suggest using every courtesy possible and gain the good will of all.

Care and Adjustments.

It has been wisely said: "Half of the ability to make an adjustment or repair is the ability to discover the necessity." One should never tinker with the car or make little changes and adjustments without first bringing some amount of intelligence and consideration to bear upon the question of what is most likely to cause the difficulty. Bear in mind that it is of little use to turn the engine over and over in an effort to start it. If it is in readiness and all is right it will start with a very few turns, and if it fails to start something is wrong and one should spend his energy in finding why it does not go rather than cranking and sweating, and many times doing even worse. If it fails to start, note the following. The switch may be on, the gasoline may be shut off from the tank, a wire may be disconnected, the batteries used for starting may be in a run-down condition, or a hundred little things might happen. Therefore, it behooves the novice to be on the watch for the little things that go wrong, for nine times out of ten it is the little things that give the trouble.

By neglecting the little details time will be saved on the road, it is true, but just as sure as fate, the day of reckoning will come. What has been saved in the garage bills and road-side repairs, will sight back to the time that has been taken for the little things. It is attention to the "little things" that count in the long run with automobile driving

Digitized by Google

GASOLINE AND THE WAR.

Part it Plays in the Great Conflict Now Devastating Europe.

From the London Petroleum Review.—For the first time in history petroleum products are playing a very important part in the international conflict of arms which is now raging throughout Western Europe. On sea as well as on land petroleum has largely replaced other forms of power. On the sea it is largely taking the place of coal, for to-day a large number of our naval units depend absolutely upon liquid fuel, while on land the internal combustion engine, deriving its power from the lighter products of petroleum is proving a most effective and rapid means of transport.

It is estimated that no less than a quarter of a million motor vehicles are now in actual service in the theatre of the European war. The French army alone has not less than 80,000 motor vehicles—passenger cars and heavy vehicles—on actual service, and this great number is continuously being added to. According to Mr. E. Lascaris, of the De Dion Bouton Company, the French army to-day only use horses in its cavalry, the army officers utilizing high power touring cars, the supply trains carrying provisions and munitions of war to the front being made up entirely of automobile trucks.

The British army in the field is depending upon automobiles entirely for transport and dispatch carrying services, and though at the time of writing England possesses nothing like the number of motor vehicles used by the French armies, it may be taken for granted that it already has on the field over 15,000 such motor driven vehicles.

Russia is somewhat behind England in the number of mechanical propelled vehicles used in connection with its military service, but even here, reliable reports estimate that Russia has now at its command nearly 10,000 motor vehicles of various types. It is over a year ago since the Russian general staff carried out a series of experiments to determine the possibilities of motor transport, and though these experiments were conducted in regions traversed by very bad roads, the motor vehicle proved its great value over all other means of transport, and, as a consequence, large numbers were immediately ordered for army use.

In the case of Germany, that country is particularly well equipped with motor vehicles, and if the figure were placed at nearly 100,000 the actual facts would not be exaggerated.

From the Petroleum Gazette.—To the above uses of the products of petroleum should be added those of the ships and other craft of the air as well as of the land and sea. Despite the reports of their enemies, each of the contending countries appears to have had substantial supplies of these products on hand and to be finding means of obtaining additional supplies as the war progresses. Germany is in the poorest position as to furnishing such supplies from her own resources or replenishing them from other countries, but reports that Germany is facing a famine in these products should be received with a good deal of reserve and consideration of their source of origin. Moreover, it is to be remembered that, although gasoline is most desirable for use in internal combustion engines, there are various emergency substitutes for it, including denatured alcohol, to whose manufacture Germany has been lending the most encouragement, and of which it is the chief producing country.

Samuel G. Blythe says this in The Saturday Evening Post: It has been an axiom of war since wars began that an army travels on its belly. This war, which is the greatest of all wars, has made it necessary to revise that statement. As it now is, an army travels on its gasoline.

Food, next to men, is the oldest factor in war, and gasoline is one of the newest. Of the two, gasoline —or petrol, as they call it over here—is the more important, because, as modern armies are organized and used, as well as from the sheer size of them, there would be little food for the soldiers if there were no gasoline.

The line of battle in the struggle going on in France as this is written extends for more than two hundred miles. Though there is no actual count, it is probable that between three and four million men are engaged in the fight, either directly or indirectly. If these men are not fed they cannot fight. Imagine the difficulties of transporting by wagon food enough for several million men stretched along a broken countryside more than two hundred miles in extent —a battle line extending approximately for example from Washington, through Baltimore, Wilmington, Philadelphia, Trenton and Newark, to the city of New York. Think what it would mean to have nothing but horses and wagons laboriously to take back the wounded and to do all the various sorts of transportation work required by forces so vast as those of the Germans, on one side, and of the allied troops of France and England on the other. No quartermaster's department and no commissariat would be equal to the task. As it is, the supplies of food and ammunition are brought forward expeditiously, and the wounded are taken back comfortably; and this is all due to gasoline.

Some time ago, when I was in Germany, they told me that the taxicabs of Berlin and other German cities were then made on War Department specifications—that is, the General Staff provided the measurements for the taxicabs that were to be used by the civilians, and stipulated the sort of engines to be installed, and all that. I thought my informant was joking, but he was not. He knew what he was talking about; for, as soon as war came the Germans took the taxicabs, and made wonderful use of them. I do not know whether the French War Department went so far into the detail of the matter; but I saw eight hundred taxicabs in one place in France, which had been commandeered from the streets of Paris for use in war. I understood that the French had as adequate realization of the importance of gasoline as the Germans.

Waging War with Gasoline.

One of the first calls issued, after war was declared, was for automobiles. They were taken by thousands. In France almost every private automobile was used. The streets of Paris were absolutely stripped of the automobile omnibuses. I have not been in Berlin as yet, but I am quite sure that the Germans took great numbers of automobiles and busses. Indeed, I have seen some Berlin automobiles in Belgium; plenty of them, in fact. In England the government took over the automobiles and about half the busses, together with a great many of the big, privately owned automobile delivery vans.

A courier from the front no longer dashes up on a foam-flecked steed. Instead, he comes in a high-

Digitized by Google

powered automobile. A messenger carrying dispatches from one part of the battle line to another does not lean down on the neck of his horse and gallop madly through a rain of bullets. Instead, he leans over the handles of a motor cycle and goes chugging on his errand at sixty miles an hour. There is no slow process of the wounded in ambulances drawn by horses or on stretchers carried by comrades. The wounded are put in fitted motor busses and delivery vans and hurried to hospitals at thirty miles an hour.

If it is necessary to send a detachment of infantry, say, from one point to another, and speed is demanded, the soldiers are crowded into taxicabs and shifted in an incredibly short time. Automobiles are constantly dashing about in the rear of the battle lines. General Joffre, the commander of the forces of the Allies in France, uses racing machines of the highest power, and can go from one end of the battle line to the other in less than four hours, for he travels at sixty miles an hour. No staff officer goes anywhere on a horse. He uses an automobile.

More than that, the Germans, and presumably the French, have taken auto delivery trucks of the heavier type and mounted field guns on them. These can be moved in any direction almost instantly. They constitute the most mobile artillery the world has ever known. In other wars artillery was shifted by horse or by hand. In this war some of the lighter guns are automobile guns, and they can be transferred from one point to another while horses are being brought up.

The Belgians have built many barbed-wire entanglements, and so have the French; but gasoline makes these seem like paper obstructions. The Germans have heavily armored automobiles with great knives in front and steel frames running back over the tops of the cars. With these tremendous clippers they charge full tilt at the barbed-wire obstructions and dash through them. The knives on the fronts of the cars cut the wires and the steel frames protect the men operating the cars. Also, there are armored automobiles that dash about the country carrying riflemen, and light rapid fire guns that do their share of execution. Automobile trucks bring up the ammunition.

It is in the commissariat, however, that the automobiles are most useful. They prove that the army travels on its gasoline. Great trucks bring supplies of food to certain bases. Light automobiles take loads of this food, and distribute it along the line, scooting back and forth, from base to given point of deposit and back again, making quick trip after quick trip, and covering the distances and doing feats of delivery that would be impossible for horses. Thus, too, by means of the smaller autos the men at the front are in constant and rapid communication with all points in the rear. The mobility of these great armies has been doubled and probably tripled by the gasoline engine.

The German system is evidently the result of long preparation. The Germans were ready. When their army is moving there is a constant procession of small automobiles—or comparatively small ones—running back and forth between front and rear, in certain well-defined lanes, bringing up whatever may be needed from the big trucks that labor behind but move far faster than any teams of horses could. The Germans use automobiles for every possible contingency save the shifting of their great siege guns. These are so big and so heavy that they are driven by thirty horses.

It is not only for trucking or for transportation purposes that gasoline is indispensable. Gasoline is the motive power for the engines of the aeroplanes. As warfare is now conducted the flying corps of each army is one of the most useful arms of the service, if not the most useful. The airmen perform prodigies of valor in scouting, in determining locations, in finding ranges, and in plotting out the lay of land. It is a good example of the repression of the British War Office that none of the English papers printed a word about the flight of the English aeroplanes to France.

That was the most inspiring sight of this war. Fully thirty of them—perhaps more—rose one day and flew, like a great flock of white-winged birds, straight across the Channel and landed without a mishap. Since that time these aeroplanes have been hovering over the lines of the enemy, finding ranges for the artillery, and doing many other hazardous things. The French have a greater number of them and so have the Germans. The aeroplane as a factor in war is as common as the automobile.

Shooting Into the Air.

The greatest value of aeroplanes is in finding ranges. In these days, in the formal engagements, the riflemen and the artilleries shoot at marks they cannot see. A man shooting from the ground can see about fifteen hundred yards. Frequently he is shooting at an enemy two thousand yards away. The artillery is behind the rifles. So the airship flies straight over the enemy's line, determines the range, flies back and communicates it to the artilleries. Then, with the range determined, the artilleries can land their shells at any given point with the utmost precision.

The bomb-dropping feature of airships of whatever sort is rather futile. Though an airship can find a range for a gun, it cannot apparently drop a bomb with any precision from any considerable height. Such bombs as have been dropped have evidently been dropped in the hope that they might hit something, rather than in the expectation that any precise thing aimed at would be destroyed. But the menace of the airship is strong in the minds of the people, especially in London. After one or two bomb-dropping experiments by the Germans from aeroplanes over Paris the Parisians discovered there was little danger from that sort of warfare, and watched the maneuvers of the German Tauben with interest but without much fear. However, the English have had no experiences as yet, and they are afraid of airships and of Zeppelins.

An item of news that was not printed in the English papers, but that had wide circulation none the less, concerned an alleged statement by Count Zeppelin. He was asked when he intended to send some of his airships over to London. "That will come in due course," he is said to have replied. This, combined with statements that many new dirigibles and many more airships are being made by Germany, caused considerable nervousness in London and made that warning by the Admiralty rather necessary; for all airships look alike to a scared com-

Digitized by Google

munity, and there is no doubt there would have been an attempt to destroy any that should appear.

Without gasoline, these huge armies would be practically helpless, for in a battle line as far flung as is the present one, and as will be the battle lines of the future if this battle is not decisive, the delay in communication would be fatal; in fact, such battles would be impossible, because of the lack of the mobility of the troops. It is true that the soldiers, after railroad trains have been used to their extreme advantage march many miles, just as did the troops of a hundred years ago, both in the advance and in retreat; but the number of men engaged in any battle in the world's history was so much smaller than the number engaged in the battles of to-day that there can be no analogy drawn.

Gasoline is the most powerfully utilitarian of the non-human factories in this war. Without gasoline the present plan of war would be impossible. With gasoline, and the resultant uses of gasoline engines for every sort of propulsive demand, it is feasible for a general to attack with a million or two of men along a battle front of two or three hundred miles, and for another general to defend with similar numbers.

With the aid of gasoline these vast armies can be fed and moved, kept in communication, and their numbers discovered and determined. A modern army travels on its gasoline. If you have watched the dispatches you will observe that the men in charge know this, for gasoline is the first on the list of stores to be commandeered, is first of the tributes demanded from the conquered people, and is more important than food or ammunition, for without it food and ammunition would be tardy if not impossible.

Excessive Lubrication.

A repair man who specializes in Ford cars advances a very good reason for oil finding its way past the rings in the first and second cylinders of some Ford motors, particularly the first cylinder of cars that have seen considerable service, and states that it is not always necessary to fit new pistons and rings, drill the piston or to use a special plug or lubricating system. Excessive lubrication of the first cylinder is due, states the repair man, to the front end of the crankcase being lower than the rear, or in other words, the supply or level of the oil is such that the connecting rod of the first cylinder dips deeper than the others, resulting in over lubrication. The supply should be the same under each rod, but with the front of the crankcase lower than the rear, too much oil is trapped in front as it cannot very well run up hill.

The remedy is simple and inexpensive. It consists of leveling up the crankcase by raising and blocking up the front end of the motor. This can be accomplished by placing a pad under the crankcase front frame bearing. If there be a decided pitch to the crankcase it may be necessary to use a block that will require longer spring clips. The alignment of the motor and universal joint will not be affected; in fact, it will be improved.

Before beginning the work it is advisable to inflate the tires to their normal pressure, and there should be at least one person occupying the front seat. When the front of a car is lower than it should be it is generally due to the settling of the front springs and to wear of the spring perch bolts and their bushings.—Apco Ford Dealer.

THE LIGHTING SYSTEM.

Suggestions for the Care and Use of the Dynamo or Generator.

A careful user, by the exercise of a little commonsense, should have no trouble in maintaining any electrical machine in good order and condition, but since such machines, to the majority of motorists, are a new departure, a few timely hints relating to the care and upkeep of the dynamo or generator may be welcome.

"Do not over oil" might well be displayed on all dynamos and dynamotors used in connection with car lighting and engine starting sets. The majority of users are inclined to over rather than under oil, and although ordinary bearings do not, as a rule, complain if subjected to the former treatment, over oiling in the case of a dynamo is very apt to result in oil and grease collecting on the armature and field windings.

Apart from the mess and waste occasioned, the presence of oil is detrimental to the insulation, for rubber perishes after contact with oil, and the whole covering, owing to the disintegrating action set up, is soon destroyed, leaving the winding in no condition successfully to resist the leakage of current.

The shafts of all rotating machines should be fitted with oil-throwers, so designed that excess oil from the bearings is thrown off before it can come in contact with the windings. With large machines devices of this kind are very successful, but it is doubtful if, in the extremely limited space occupied by a car dynamo, they can be relied upon to cope successfully with any great excess of oil.

A coating of oil or grease always acts as a very good dust collector, and amongst the dust small pieces of metal, copper particles from the commutator for instance, will often find a resting place. In this way a more or less conducting layer is produced, and breakdown of the insulation may result.

Again, moisture, which is very detrimental to the insulation resistance of a winding, has a much greater tendency to collect and remain wherever dust or other small particles happen to be, and for the above and other reasons it should be quite clear that over oiling is to be avoided.

If, however, oil has collected on the windings it should be carefully removed and the cause of the trouble located. For instance, it not infrequently occurs that the bearings are dirty, and that new oil is simply thrown out as soon as it is provided. In such a case the application of a little paraffin to clear out the bearings, and a fresh charge of oil should remedy the defect, while careful attention to the lubricators and waste oil chambers should prevent a recurrence of the mischief.

Trouble with Commutator and Brushes.

Excess of oil or grease is the cause of much trouble with the brushes, or current collecting device, and the commutator. The brushes must bed down accurately on to the segments, and yet be free to move in their holders, or boxes, as they are generally called. Oil, acting as a dirt and dust collector, tends to clog the boxes, and the brushes can then no longer move freely in them, so that any want of truth in the commutator will result in sparking

Digitized by Google

taking place, the result being that the copper segments will soon become pitted and burnt.

Sparking should receive immediate attention, and if it be found that the brush holders are at all dirty the brushes should be removed and the holders carefully cleaned, while further, the brushes should be watched to see that no slipping or jumping takes place, the latter often indicating that a spring has failed.

The springs are necessary to ensure good contact taking place between the brushes and the commutator, and the sparkless collection of the current. From numerous experiments it has been found that a pressure of some 2 pounds per square inch is required, and if the contact area of the brush is found, the necessary pressure can be applied with the aid of a spring balance, or judged merely by holding the brush spring off with the finger.

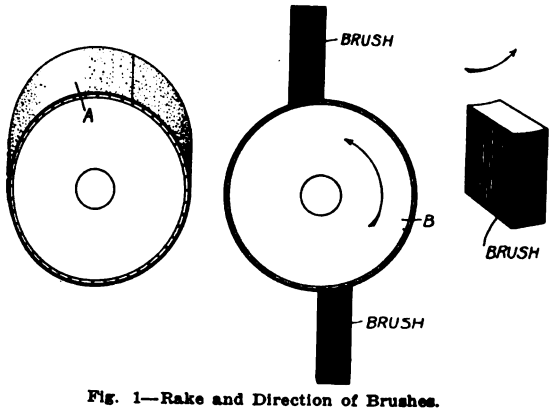

Fig. 1—Rake and Direction of Brushes.

If copper brushes be used they should be kept in perfect condition and well trimmed to ensure good contact taking place with the commutator. Carbon brushes are better, and good contact with the holder should be secured by copper plating the brush wherever it makes contact with the holder.

Insufficient brush tension makes the brushes liable to be affected by vibration, rattling taking place and the commutator frequently becoming scored, while if the springs press too heavily the commutator is worn into grooves. The contact surfaces of the brushes should be smooth and polished; if they are not, or if new brushes are required, careful bedding down is necessary.

Bedding-in the Brushes.

Select a piece of fine emery cloth of sufficient length completely to surround the commutator with its cutting surface outwards, and then fasten its ends tightly by overlapping them and joining the overlap with seccotine or some other form of glue or cement, as at A, Fig. 1. Replace the brushes, adjust the spring tension, and then slowly rotate the armature. The brush surface will be ground down to the correct shape and smoothly finished off, and it will then be in a condition to bed down correctly on to the commutator. Examination of the brushes will reveal the fact that they are generally raked as shown in Fig. 1 at B, and the direction of rotation of the armature should be such that the commutator always runs against the rake of the brush, as shown by the arrows. Further, to prevent the formation of ridges, it is necessary that the brushes should be staggered across the commutator, as in Fig. 2, for if they are placed in line half of the commutator will be worn down and a ridge be formed.

The condition of the brushes is very often reflected in the condition of the commutator, the surface of which indicates very clearly if the machine is in good running order. The color should be a rich dark brown, but a tan coloration, when there is no evidence of burning, indicates that a little oil or vaseline is required. An occasional rub with a piece of paraffin wax improves the surface, while a piece of pine makes a good burnisher for occasional use in order to keep the surface of the commutator clean and smooth.

Rough portions on the commutator must be removed by the use of glass paper, not emery cloth, and it is best to perform this operation while the machine is in motion. Dirt is also detrimental to good running, its presence being in general indicated by numerous small sparks passing from one segment to another. Dirt should be removed by rubbing, and it is very necessary to note that linen and not cotton waste must always be used.

Sometimes part only of the commutator will appear to be dirty. This is an indication of a flat, and unless it is removed by careful filing sparking will result. A fine cut file is necessary, and a circular motion must be communicated to it while in use, care being taken afterwards to remove all copper particles that have been produced. Filing up a commutator is, however, a delicate job, and it is better to put the work into experienced hands than ruin the commutator by crude handling of the file.

Chattering of the brushes indicates that the mica insulation between the segments is projecting above

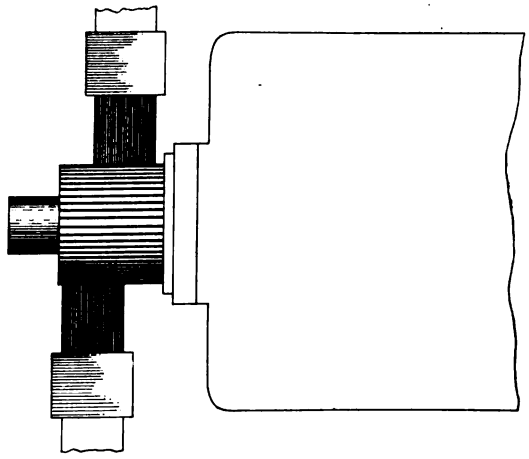

Fig. 2—Commutator and Brushes.

the level of the commutator. A few cuts with a very sharp knife is generally sufficient to remove the superfluous mica, and by placing the finger along the commutator and slowly rotating the armature any inequalities can readily be detected. A last word may be said with respect to the position of the brushes. They should be fixed and kept diametrically opposite to each other and the best position for sparkless collection of the current is to be found only by trial.

At least once in six months ball bearings should be inspected, the rough or worn balls replaced with perfect ones, and the ball run filled with graphite grease.

NEW AND INTERESTING THINGS IN MOTORDOM

BUSINESS NOTES

No Refilling Deception.

Two decisions of considerable importance to retail automobile dealers and garages have just been handed down by United States courts. The pith of both decisions is that substitution, under certain circumstances, becomes the basis of damage suit against the dealer who practices it. In two of its suits, growing out of the substitution of refilled tanks in exchange for Prest-O-Lites, The Prest-O-Lite Company, Inc., asked for an accounting of all profits which the defendants had made through substitution and through misuse of the trademark on "Prest-O-Lite," and also asked for additional damages covering injury to its good will, etc. The court allowed an injunction compelling the complete and permanent removal of the Prest-O-Lite mark from such cylinders before refilling and also enjoining the defendants "from selling, or dealing in, or exchanging, or passing off any cylinders or gas tanks or packages filled or prepared by any person other than The Prest-O-Lite Company, as Prest-O-Lite tanks or exchanges, refills, or recharges, and from applying in any way or using said trade-mark "Prest-O-Lite" to describe or to sell or to pass off any of the said gas tanks or prepared packages filled by any person other than the complainant." The effect of these decisions is to make the refiller, and not The Prest-O-Lite Company, responsible for all exchange and repair service on "refilled" tanks. The present suits are intended to establish the point that compliance by the refiller is not sufficient, and that the dealer who is handling such tanks must also comply and market them without leading the automobile owners to believe that The Prest-O-Lite Company has any connection whatever with the refilled tanks or is in any way responsible for their contents, service, repair or exchange.

Remarkable Prosperity.

Reports from all sections of the industry reflect the remarkable prosperity now enjoyed by manufacturers of automobiles and accessories. The National Automobile Chamber of Commerce recently reported the establishment of new shipping records by car makers during the first three months of the present year, and last week a canvass was made of a number of the motor car and accessory factories in Detroit for the purpose of learning the increase in the number of men employed at the plants during the last six months or so. Every plant that has to do with motor cars and trucks or parts and accessories was reported as working at full speed, some of them overtime and others with night and day shifts. In all the factories the number of employes was being constantly increased.

Coupon Book.

J. P. Forbes, of Coshocton, Ohio, is making gasoline coupon books and auto supplies coupon books that are inexpensive and widely used. Those interested should address the firm as above for full particulars.

A Snag for the Jitney.

Insurance agents report that their home offices will not accept applications for indemnity contracts on jitney buses even at the high rate of $200 per $1,000 of liability. The question of whether or not the jitney bus is a common carrier or a public conveyance as contemplated in accident insurance policies issued to individuals has not yet been settled. In response to requests from Milwaukee, the Attorney General of Wisconsin has given an opinion to the effect that the jitney bus does not come under the provisions of the public utilities act, and therefore is not subject to regulation by the Wisconsin railroad commission. Attorney General Owen says: "The jitney bus, it seems to me, is to be classed with the taxicab and the hack. Cities are not asked to turn over streets for the purposes of transportation. The jitney bus business is essentially a private one."

Big Share for Employes.

Not long ago employes of the Neumann-Lane Co., Detroit distributor for Chalmers, Pierce-Arrow and Rauch & Lang cars, were the guests at a dinner given by Wm. F. V. Neumann and Geo. E. Lane. The feature of the family gathering was the sharing of profits with all those employes who had been on the company's pay roll at least one year. The checks amounted to 24 per cent. of the yearly salary of each employe. The workers were further gladdened by the announcement that Neumann-Lane has offered a cash prize of $100 to be given to the employe of the company who at the end of the year is considered the best in the concern's employ. The superintendents and foremen are barred from the contest. The winner will be decided through a vote of all the eligible employes.

All Out for Good Roads.

It is estimated that more than half a million men will work on the highways of Pennsylvania on May 26th, which is designated "Good Roads Day." An organization of 20,000 in Blair County is already enlisted. All the motor organizations and civic clubs are co-operating with the county commissioners. Automobiles will carry the workmen to all parts of the county and back to their homes at the end of the day's work. Similar organizations have been formed in all of the 67 counties in the State and for one day at least the State roads will get plenty of attention.

Timken Plants To Be Enlarged.

Ground is about to be broken for a new forge shop and power plant for the Timken-Detroit Axle Co., Detroit. This will double the present capacity of the concern for drop forgings and the like.

The site of the new buildings is approximately 1,000 feet long, facing the present plant and on the opposite side of the street, while it is about 500 feet deep, and it is probable that the entire space will be filled with buildings.

Timken-David Brown facilities are to be increased to about double their present capacity on worm gear making when a building now under way and three stories in height of brick is completed.

A Combination Car.

The Kearns Motor Car Co., of Beavertown, Pa., has brought out a combination car known as the Kearns Trio. It is a three-in-one car and will take the form of either a runabout, a touring car or a light delivery wagon. This three-body car is different from previous combinations because the entire body is not changed but the part back of the fore-door. By slipping on the extra rear portions of the different bodies, the three combinations are made. With this arrangement the car is always the same from the radiator as far back as the rear end of the door to the driver's compartment. Beyond this point the additions which are slipped in place make the car either roadster, touring or commercial. The car can be bought in chassis form without any of the bodies, or it can be bought with any one of the three or the complete outfit.

Dealers Organize.

Practically every automobile dealer in Milwaukee, Wis., is a member of the recently reorganized trade association, now known as Milwaukee Automobile Dealers, Inc., which has a membership of thirty-two concerns. Headquarters have been established in the Wisconsin Hotel. An insignia has been adopted which will be extensively advertised, being reproduced on the windows of the concerns identified with the association and on all of the cars of the members.

From "8" to "4."

The Cummins Auto Sales Co., of 402 Mt. Vernon avenue, Columbus, O., which January 30th, introduced the Monitor "Eight," the machine marking their entrance into the automobile manufacturing field, have decided to abandon the eight cylinder car and in the future will devote their entire attention to the turning out of a Four.

The New $490 Chevrolet.

Deliveries on the $490 car of the Chevrolet Motor Co., New York City, are now scheduled to commence. The car was disclosed at the New York show last Januarv and styled the "Four Hundred and Ninety," and is a five-passenger machine, with 102-inch wheelbase, 30x3-inch tires, 20 horsepower motor and a number of original detail features.

No More Half Registration.

One of the measures affecting automobiles that were passed by the New York State legislature was the Hewitt bill, striking out of the present motor vehicle law the provision that owners of pleasure cars were to pay only half of the registration fees for their car after they had been registered under the Callan law for four years in succession. Quite a number of automobile owners throughout the state were prepared to take advantage of this provision when it became effective this year, but because of the additional clerical work attached to check-

Digitized by Google

ing up the vehicles eligible for the half registration fee opposition was offered by the Secretary of State's office, and the Hewitt bill was the result.

Over $15,000,000 in Ford Car Rebates.

It is announced that $50 will be repaid to every buyer of a Ford car during the year from August 1, 1914, to August 1, 1915. The plan called for a rebate upon the purchase price of each car if 300,000 cars were built and sold. It appears that this production is now insured and with a month to spare. If the production reaches 325,000, the fulfillment of the plan will mean the payment of $16,250,000 to purchasers.

Cartercar Plant to be Closed.

It is reported that the Cartercar plant, at Pontiac, Mich., will be closed about the 22d of May. It appears that it is the intention to manufacture in this plant a new light six car, which the General Motors Organization has now in the process of development. This car will probably sell for less than $1,000. Whether the principle of a friction drive car is to be abandoned is not stated.

Business Growth.

The Positive Supply Company, of Davenport, Iowa, manufacturers of portable steam tire vulcanizers have just moved into the new three story building, the Positive Building, at 209 East Second Street. They have increased their capitalization and have added to their line of goods.

New Car-Nation Model.

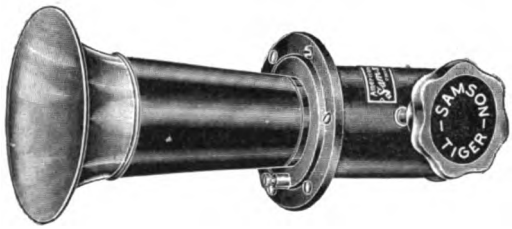
The Car-Nation Motor Car Co., successor to the American Voiturette Co., of Detroit, Mich., is busily at work turning out cars for the 1916 season in the plant at Lawton and Buchanan streets. The cars will be an entirely new model, of the low-priced light-car type.

A Premium Offer.

The National Auto Supply Company, 77 Chambers St., New York, have a free premium offer in their new 1915 catalogue, which will be sent to anyone who will address the firm as above.

BODY AND TOP

The Gemco Bumper.



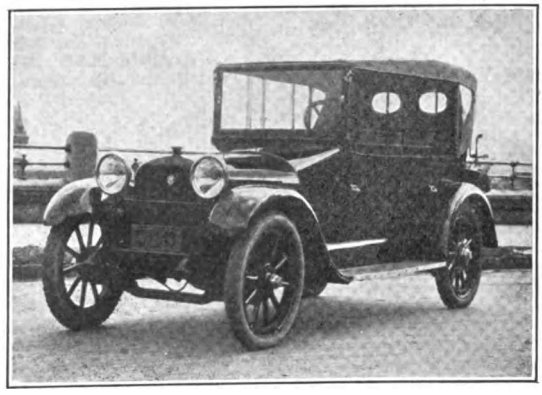
During the past two years the use of automobile bumpers as a protection has become almost universal. At first they were thought only necessary in the large cities but motorists everywhere now realize the advantages of this equipment. A substantial, well constructed bumper will protect the radiator, lamps, springs and wheels in severe collisions and many thousand dollars have been saved drivers by this protection. The Garage Equipment Manufacturing Company manufactures the "Gemco" Universal End Thrust Bumper which is applicable to all standard cars. The exclusive feature is the point of attachment. This abuts the end of the frame which is the strongest place. "Gemco" Bumpers are furnished with a large variety of bars, including diamond, channel, round and rectangular in different sizes. The Diamond Bar is a new bumper added to the line this season and, in addition to the protective value, lends greatly to the appearance of a car.

The Friction Shock Absorber.

It is beginning to be felt by car owners that shock absorbers are pretty nearly indispensable. This is especially the case with the low-priced automobiles where the wheel base is short. The Friction Shock Absorber Company, of Kingston, N. Y., are making a shock absorber which is placed near the axle where the rebound is greatest. This makes the rear seat as comfortable as the front seat and does away with the discomfort of riding just over the axle and rear wheels. A shock absorber of this sort also lessens the shock to the machinery and springs which in itself is a decided advantage. There is nothing that will rattle in this shock absorber and nothing that wears to any extent or requires care or attention. In sending inquiries the model of the car, the style of body and the year the car is made should be stated so that proper fixtures may be furnished to attach to the body or springs.

Dealer Co-Operation.

During the present chaotic conditions of merchandising, the automobile and accessory dealer will be pleased to learn that there are manufacturers who do not underestimate the value of dealer co-operation as an economic factor in distributing their product. There is only a very small percentage of the entire reading public that is interested in automobile horns. Who, then, pays for this wasteful, general advertising? Either the quality of the horn must be cheapened, a list price established entirely out of reason, or the dealer forced to be satisfied with less profit. Maybe all three factors stand their share of the burden.



While Samson automobile horns, manufactured by the American Electric Company, of Chicago, are well known to the trade, and are effectively advertised to the consumer by "dealer helps" they are not advertised through general mediums. The policy of the manufacturer is to co-operate with the dealer by giving him a gross mark-up that will more than merely cover handling charges, and by giving him a horn with the greatest possible value. The Samson-Tiger hand horn which is being featured by the manufacturer is of a new type construction; simplicity is its most salient feature. There are no springs, plungers, dogs, levers, ratchets, or other complicated parts to give trouble, but is shaft driven. The advertising of the American Electric Company of Chicago, now appearing in a number of the trade journals, carries a vital message to the retail merchant that is full of truths.

New Ford Fenders.

A specially designed rear fender to be used on Ford commercial cars is being manufactured by the Superior Lamp Manufacturing Company, of 136 West 52d St., New York City. These "Superior" fenders are made up in pairs, with irons complete, all ready to attach to any kind of delivery body that may be put on the Ford chassis. The present rear Ford fenders are not practical where a delivery body is being used, and these specially constructed fenders are a necessity where a delivery body is used. They have the latest design curve, same as the 1915 rear Ford fenders, and are made of extra heavy steel metal to withstand the constant strain they are subjected to.

A New Convertible Top.

Neither the oppressive sun nor a sudden storm has much effect when using the new H-W All-Weather Convertible Top. It can be easily converted into a closed weather-proof covering in three minutes and it makes an unusually handsome appearance, as may be seen by the illustration. It takes just two minutes to put in or take out the eight windows. When not in use these windows are carried in a neat box placed

The Convertible Top.

Digitized by Google

beneath the front seat. It really gives two cars in one, because with it the owner can have an open car for touring and a closed car for town use. Only the finest material is used in its construction and it is strongly guaranteed. It is made by The Hammons-Williams Convertible Top Company, 529 Marbridge Building, Broadway and 34th St., New York.

The Beartone Signal.

The Oakes Company, Indianapolis, Ind., manufacturers of the Beartone horn and fan combined, have announced that the price of this combination has been reduced for the Ford type. They state that for some time past they have been working day and night in order to meet the increased demand for this product. The Beartone is not only a reliable warning signal, but is also a fan which they guarantee. It is in the logical place for a fan, under the hood, in front of the motor. This is a motor driven horn without current consumption and does away with battery wires, etc.

The Friction Shock Absorber.

This is made by the Friction Shock Absorber Company, of Kingston, N. Y., and it is claimed with confidence that it will do the work required and stand the wear. It is placed near the axle where the rebound is greatest and where it can do the most work. It does not check the downward action of the spring until the end of the movement and will then convert the upward shock into an easy recovery and a normal position. Its simplicity and common sense construction should make it extremely popular.

Samson Automobile Horns.

This automobile horn was undoubtedly named properly. It is unusually strong and durable and attractively finished. The price is as low as any one can think of asking for an efficient signal. It is made by the American Electric Company, State and 64th Sts., Chicago.

GARAGE AND REPAIR SHOP

Steam Vulcanizers.

In view of the fact that vulcanizers can now be purchased at a very low cost and at a mere bagatelle of their usefulness, no car owner should neglect the small cuts in his tire casings. The Wizard automatic steam vulcanizer is adapted for both tubes and casings of any size. It is extremely simple in construction and there is no reason why it should not last practically forever. The manufacturers of this vulcanizer, The National Motor Supply Company, 5636 Euclid Ave., Cleveland, Ohio, offer to ship it by mail prepaid and allow a free trial for ten days. If it is not entirely satisfactory it may be returned and the money refunded.

Useful in the Garage.

The Weaver garage press is now used in a good many up-to-date garages and in the case of heavy repair work it is often almost indispensable. The leverage of this press is 1500 to 1, and it is easy to see the tremendous power that it will develop in straightening an axle of a shaft or in work that requires unusual power. It is strong, compact and light, considering the fact that it will enable one man to do the work of three. It is made by the Weaver Manufacturing Company, Springfield, Ill.

An Electric Vulcanizer.

The Corbett & De Coursey Company, Columbia Bank Building, Pittsburgh, Pa., make a portable electric vulcanizer, to operate on a 6-volt storage battery, which

Corbett and De Coursey Vulcanizer.

is common on automobiles. It is furnished complete with 6 ft. of flexible, reinforced cord and a bayonet type plug, which may be attached to the exploring or regular lamp socket. The vulcanizer costs very little to use, as it takes less current to operate than does the lighting of the car.

The total weight, including serviceable canvas bag, is only 2 lbs., and, as the vulcanizer takes up very little room, it may be easily carried in the tool box. A standard thermometer, with which it is equipped, allows the heat to be maintained constant at 275 degrees, and, as it may be used under any weather conditions, a patch can be vulcanized out on the road as well as in the garage.

Pipe Threading Tools.

A new attachment called the Internal Guide with Reamer Point, manufactured by the Greenfield Tap and Die Corporation, Greenfield, Mass., is attracting some attention and its success seems to be assured. This guide takes the place of the various forms of external or bushing guides which have been the only method heretofore of guiding the dies in pipe stocks for a straight thread. This guide not only guides the die in making its first threads, but reams the burrs from the inside of the pipe as it enters, and thus the extra cost of a burring reamer is eliminated. The Trio Pipe Stock, which contains three different cutting sizes of Little Giant dies, is now fitted with this form of guide as is also the Duo pipe stock, which contains two cutting sizes. In the case of the Trio stock the manufacturers claim that this tool takes the place of seven distinct tools that would otherwise have to be used, namely, three stocks and dies, three burring reamers and one tap and reamer wrench. This tool has a removable handle and the whole thing can be packed in a very small space in the workman's kit.

Trio Pipe Die Stock.

New Welding Outfit.

It seems to be generally admitted that anyone who has a garage or repair shop should, under no condition or circumstances, try to get along without a welding outfit. If he can get an outfit that will weld, cut and remove the carbon from the cylinders in one combination and at a low price all the better. The Imperial combination outfit made by the Imperial Brass Mfg. Co., Cor. Harrison & Racine Ave., Chicago, is here illustrated and shows a torch arranged for welding with the cutting attachment removed, and also a torch arranged for cutting with the welding head removed. With this apparatus there also goes a decarbonizing torch. An apparatus of this kind will soon pay for itself in an automobile repair shop. It will weld anything in metal and will cut any thickness in steel or wrought iron and of course is a great labor saver. It can be easily carried wherever the work is required and does the work at a very small cost.

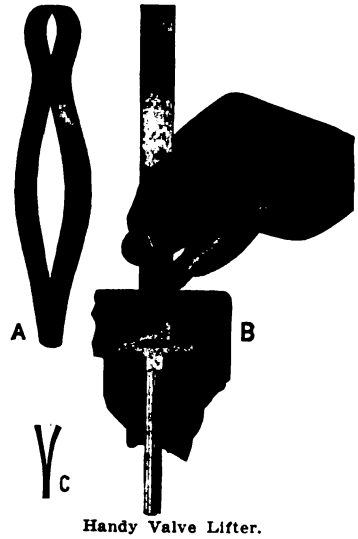
Pitless Turntable.

A special size turntable for Ford cars has been placed on the market by the Pitless Auto Turntable Co., 24th and Broadway, Kansas City, Mo. The turntable consists of two runways centrally pivoted by a king pin and mounted on ball bearing wheels. There is a lock to secure it from turning in running on and off the table. When the track is set in concrete the turntable is ⅞ inch above the floor level, making it hardly noticeable in running on and off the table. This turntable was manufactured to meet the demand for a low priced product without sacrificing the quality.

Cuno Ford Timer.

Missing in your Ford car will be stopped if you install a Cuno Ford Timer. This timer is made by the Cuno Engineering Corporation, 80 South Vine Ave., Meriden, Conn., and it will be mailed on receipt of price, which is remarkably low, to anyone desiring it. Satisfaction is guaranteed. Jobbers and dealers should write for attractive proposition.

The Stewart Garage Heater.



Although the warm weather is coming on it is well to install a garage heater now, when special low prices are being made. A catalogue of the Stewart garage heater gives a good deal of valuable information, and it will be sent free to any one asking for it, by addressing Fuller & Warren Company, 320 Madison St., Troy, N. Y.

Will Pick the Valves Out.

The Fulton Company, Milwaukee, Wis., has recently placed upon the market a valuable tool known as the "Handy Valve Lifter." It is constructed of one piece of spring steel, as shown in the illustration. It goes in the port hole of an engine, and its knurled ends engage the sides of the slot in a valve by a slight

Handy Valve Lifter.

pressure of the fingers, and the valve may then be easily and securely removed as shown. The illustration also shows the ends of the tool that spread apart when the spring is pressed together, like sheepshears. These ends have a double knurling on the outside, which engages securely the sides of the slot in the valve. This handy valve lifter is something that is absolutely new. It is a labor-saving device that should be in every garage, and should be a part of every mechanic's kit.

The Eyes of the Auto.

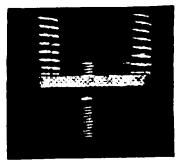
Illustrated herewith is a tool which is called the "Red Devil" glass cutter, No. 263. It has a genuine hand honed steel wheel, tested and inspected by an expert and cuts circles from 2 to 22

A New Glass Cutter.

inches in diameter. Garage owners and repair shops would do well to provide themselves with one of these glass cutters and save money by cutting their own headlights. They are marketed by Smith & Hemenway, 179 Chambers St., New York.

FOR THE MOTOR

The Chain Carbon Remover.



The Michener Chain Carbon Remover has been used for a good many years now and has always seemed to give the highest satisfaction. It has one special merit inasmuch as it is simple, and the engine itself really does the work. Probably a good many of our readers already have this carbon remover and do not need to be told anything about it. New readers may be glad to know that it is inexpensive and does the work thoroughly. In some cases, it is desirable to use two chains, as in a four cylinder motor, and three chains for six cylinder motor. This does the work more quickly and is sure to remove all carbon deposits. It is made by E. S. Michener, New Castle, Pa.

The New Ford Radiator and Hood.

The National "V" Type Radiator and Stream Line Hood adds a supreme touch and gives an air of distinctiveness and quality to Ford cars. The circulation of this radiator is rapid, the water will not boil and it has a great cooling capacity. It is stated freezing will not injure it. This radiator is made of polished brass or black enamel, and the price, complete, is small. The Stream Line Hood for regular Ford radiators can be purchased separately. The Universal Car Equipment Company, 62 Jefferson Ave., Detroit, Mich., are placing these Ford specialties on the market, and further information regarding them will be furnished upon request.

Valve Grinding and Removing.

The Perfect valve grinding set is a Ford specialty which actually saves money for the car owner and offers a means of obtaining the maximum efficiency from the motor at all times. The explicit instructions that accompany the set make it possible for the most inexperienced driver to grind the valves and remove the carbon from the motor and

Perfect Valve Remover.

on account of the ease and rapidity with which the valves may be removed with the Perfect valve spring lifter this most important work can be accomplished in a very short time. The advantage in keeping the valves ground and the cylinders clean is more power, longer life to the motor and more mileage per gallon of gasoline; also eliminates overheating and knocking when climbing hills, caused by the carbon deposit in the cylinders.

The valve spring lifter operates on an entirely different principle from any other tool made for this purpose. It compresses two springs at once and holds them up securely. A few turns of the nut are all that is required to raise the springs high enough to remove the pins or washers from the valve stems. The valves may then be taken out, ground and replaced without further troubling the springs. The valve spring lifter and grinding set are made by the Winton L. Smith Machine Works, 78 Clinton St., Newark, N. J.

The Peerless Piston Ring.

This new piston ring has a lock joint that makes the leakage of compression practically impossible. Moreover these piston rings are what may be termed eccentric rather than concentric and this ensures uniform pressure at every point of the cylinders. It is easily installed, easy to sell because there is a money back guarantee that goes with it, and there are no loose pieces to drop out. Judging from an examination of this piston ring it is in every way suited to the requirements for gasoline motors and it has strength and flexibility. It is made by Larson and Hilker, 19 South La Salle Street, Chicago.

No-Leak-O Piston Ring.

The No-Leak-O piston ring, manufactured by the Automobile Accessories Company, 816 West North Ave., Baltimore, Md., and which is illustrated herewith, is made in one piece and has no crevices to absorb oil, creating carbon to destroy the efficiency of the ring. They

are individually cast and finished in the very best manner. These rings give high and lasting efficiency and are backed by strong testimonials. They save gasoline, oil and repair bills, as well as time, and the price is right. A special proposition is made to jobbers and those interested should address the company as above.

The Micro Piston Ring.

Automobilists seldom realize the direct and grave influence of piston ring construction upon the performance of their cars. Perfect compression is essential and the piston rings should adequately perform their function in confining the explosive mixture to secure it. Owing to the fine uniform grain of these piston rings they can be taken off the piston any number of times without the slightest danger of breakage. Shipments of small orders by parcel post is most economical, and can be obtained by addressing the Micro Piston Ring Company, 1960 Broadway, New York.

Carbon Removed Quickly.

It is claimed that by the use of the carbon remover made by the American Oil Products Company, Buffalo, N. Y., the job can be done in from ten to twenty minutes, and done satisfactorily. The firm has some splendid endorsements as to its effectiveness and the price is low. The cost of removing carbon by this means is said to be from 5 to 12 cents per cylinder.

Perfection Piston Rings.

The name of these pistons rings was chosen because it indicates their quality. They are said to be absolutely perfect. They are put on the pistons without being stretched and this is something that is not possible with a one piece piston ring. They are made by the Automobile Construction and Eng. Company, 3326 Ludlow St., Philadelphia, Pa.

Repair and Assembly Parts.

A wide variety of repair and assembly parts for storage battery can be secured by addressing Walter L. Thompson, 655 West 43d St., New York. These parts include plates, jars, separators, terminals, solution and sealing compound.

CARBURETION AND IGNITION

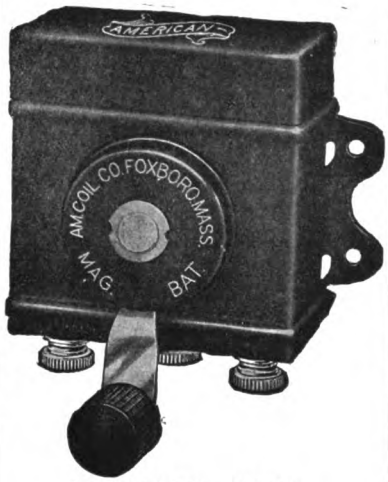
Spark Plug Business.

Recently papers were signed which transferred the entire business of the Frontier Specialty Company, Buffalo, N. Y., to the Champion Spark Plug Company, Toledo, Ohio. This very naturally marked the dismissal of the suit brought against the Champion Company by the Frontier Company, in November, 1914, for infringement of the Simms and Shea patents, which cover priming plugs.

The Champion Spark Plug Company states that the licenses issued by the Frontier Specialty Company to the Benford Manufacturing Company, Sharp Spark Plug Company, Emil Grossman Manufacturing Company, Rajah Auto Supply Company, Bigsby Manufacturing Company, Reflex Ignition Company and A. R. Mosler Company for the manufacture of their respective priming plugs, will still remain in force under the same conditions as before. The "All-In-One" plug with priming cap, will henceforth be manufactured by the Champion Spark Plug Company, along with the rest of the well known Champion line.

The Benton Spark Plug.

This spark plug is claimed to minimize or entirely avoid common defects, to resist fouling and to permit easy cleaning without breakage or injury, and is made with variations to assure constant high motor efficiency under all conditions. The insulator is extremely thin sheet mica



spirally wound upon the central electrode and forced to a permanent gas and oil tight joint within a steel bushing. The layers of mica extending each way from the bushing overlap each other and cannot become loosened or broken. The mica above the bushing is enclosed in a porcelain spacer which could be cracked or even entirely removed without short circuiting the plug.

The insulator is easily removed for cleaning. The cleaning operation can be repeated any number of times and the joint always closed gas-tight. Battering of wrench and thread surfaces is prevented by case-hardening.

The Benton Plug has been made slow to foul and overheat; first, by almost closing the shell and leaving little gas space within, which minimizes heat generation and carbon formation here; second, by a heavy metal shell in contact with the cylinder to conduct the heat away rapidly; and third, by shaping the internal passages so that exploding gas blows away from the insulator a large percentage of the carbon that would otherwise be deposited. The Benton Plug is made by L. F. Benton Co., Vergennes, Vt.

The American Master Vibrator.

This is made by The American Coil Company, Foxboro, Mass., and has some qualities of decided and unique merit.

American Master Vibrator.

It can be attached to the coil in place of the switch and thus is easily understood. It is well finished and designed especially for Ford cars.

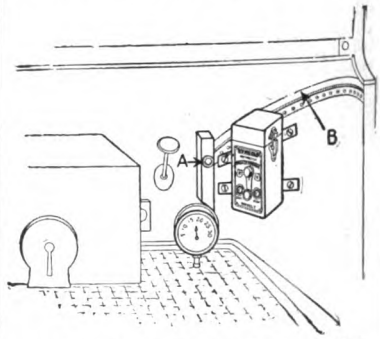
Monarch Indestructible Ammeter.

The Hercules Instrument Company, Inc. of Mount Vernon, N. Y., have acquired from the Benford Manufacturing Company of that city the sole rights to manufacture and sell the Monarch Indestructible Ammeter, and also all patent rights. The new company announces that they intend to put the ammeter before the market in a way which no other ammeter manufacturer has ever before attempted. In addition to marketing the Monarch Ammeter, the new company is also placing on the market an indestructible voltmeter and an indestructible battery tester.

A New Spark-Plug Guide.

A. R. Mosler & Co., of Mount Vernon, N. Y., have just issued a booklet with the title of "Mosler on Spark Plugs." The publication, which is attractively printed and arranged conveniently in size and shape suitable for pocket use, contains an interesting statement by A. R. Mosler himself, explaining the why and how of the spark plug, and also lists all prominent makes of pleasure and commercial vehicles and motor cycles, in handy index form, giving the kind, type and size of plug recommended by A. R. Mosler & Co. for use in connection with each engine. The booklet is intended for free distribution. A copy will prove useful to the dealer and his clerks, as well as to the car-owner, and we prophesy a ready welcome for it.

The Easily Cleaned Spark Plug.



The Stonebridge spark plug can be cleaned without removal from the car. It is said to need no adjusting whatever and can be tested without the use of a tool of any sort. The manufacturers have a proposition to make which they say means cash to dealers. This proposition is of the co-operative kind and as the demand for this spark plug is increasing it will pay dealers to write for particulars, addressing the Stonebridge Sales Company, 10 Wall St., New York.

Lighting and Starting.

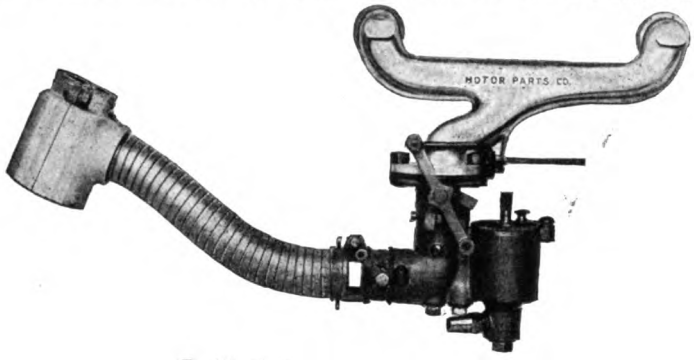
The Lead Batteries Company, of Chapel Street and Lister Avenue, Newark, N. J., renews the standard makes of batteries and has some territory for live agents to use their device and system. The business ought to be a good one, for instead of going out of existence the battery seems to be gaining in popularity.

Master Vibrators for Ford Cars.

The illustration shows the position occupied by the New York Coil Company's master vibrator on the 1915 Model T Ford cars. It will be seen that provision is made whereby the bracket may be shifted higher on the right hand side, which allows screws to find a solid foundation in a wooden sill provided under the upholstery. In this position the vibrator is readily accessible and does not take up any leg room in the car. Wires provided with connections are supplied with the vibrators, which enables the owner to make the proper connections to the magneto to secure

N. Y. Coil Co.'s Master Vibrator on New Ford Model.

the best results from both ignition and the lighting system. All models put out are equipped with these additions so that they will fit either the old models or the new 1915 model, enabling the dealer to supply all models from one stock.

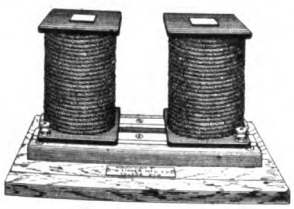


Two New Spark Plugs.

The Perpetual Spark Plug Company, of Dunmore, Pa., make spark plugs which they claim do not depend upon the electric spark to ignite the gas. They likewise maintain that these spark plugs cannot be short circuited in a Ford car. They are useful in the case of scored cylinders, resulting in poor compression, as this will not have a tendency to foul them. They are on sale at most first-class garages, but if your dealer does not have them, write to the address above and ask for particulars concerning their free trial proposition.

Digitized by Google

A New Carburetor.



The Model O 4 Zenith with special manifold and other attachment makes it possible to equip a Ford car with a carburetor which insures easy starting, good low throttle and slow speed running conditions, quick pick-up and getaway, and the maximum speed and power with minimum gasoline consumption. The strongest appeal of the Zenith to the motorist lies in its absence of moving parts and adjustments. There can be no wear in the elements which give automatic carburetion. Economy is another strong feature of the Zenith. It cannot waste fuel because a definite rate of flow determined by the manufacturer follows with exact precision the needs of your motor. The compound nozzle of the Zenith covers every range of speed from high to low. The Zenith on your Ford car means more power, speed, flexibility, easier starting and quicker pick-up. The outfit consists of Model O 4, 1-inch Zenith carburetor, special manifold hot-air drum and tube and special gasoline and throttle connections. The attachment is readily placed without adjustment or any changes whatsoever. It is made by the Motor Parts Company, 818 North Broad St., Philadelphia, Pa.

Zenith Carburetor and Attachments.

A New Magnet Charger.

We have had a good many inquiries in relation to magneto chargers, and for information as to how this work can be best done. The Quality magneto charger, made by the Sypher Manufacturing Company, Toledo, Ohio, is a result of long experience and careful study. It is so simple that a novice can do the work and is strongly constructed, so that it will stand up under much abuse. It weighs 20 pounds and has all the strength that is ever needed. It is wound for 6 volts, 110 volts and 220 volts. It will not operate on alternate current. The firm furnishes a set of pole pieces by which a set of Ford magnets can be recharged without removing them from the flywheel. It is guaranteed for five years and garage keepers ought to be able to get enough work to pay for it quickly.

Quality Magneto Charger.

The Pumpelly Battery.

This new battery takes a long step in advance and is marvelous, efficient and durable. It has been submitted to the most searching tests and is receiving nothing but high praise and friendly words. It competes in price with the old type batteries of an inferior quality and it is made for every type of automobile starter and every make of car. The manufacturers are making a special proposition to garagemen, and they would do well to write the Pumpelly Battery Company, Indianapolis, Ind., for full particulars.

The Right Spark Plug.

The Jumbo spark plugs, made by Gibson-Hollister Company Co., 3389 Washington Street, Boston, Mass., is designed to cover everything that is needed in the way of an ignition plug, and they are sold with the strongest sort of a guarantee that they will answer all requirements. It is said to behave all right under all sorts of conditions and it is jumbo big, bull strong and dirt cheap.

The Handy Valve Lifter.

This is a small tool and will save its price in a short time in any garage. It will remove the valve of an automobile in a half a minute and is made by The Fulton Company, 723 National Ave., Milwaukee, Wis.

Marko Storage Batteries.

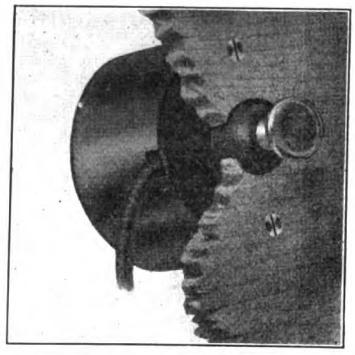
It is undoubted economy to use the best batteries that money can buy. This automobile owners are beginning to understand, and when the spring overhauling of automobiles is at hand, it is a good time to stock up with batteries of this sort. The Marko storage batteries are made by Paul M. Marko & Co., 1191 Bedford Ave., Brooklyn, N. Y.

A Good Spark.

The Platinum Point Perfector is designed to clean spark plug points and is far superior to a file or emery. It is made by the Hinsdale Auto Co., Hinsdale, Ill., and costs little.

Save Your Gasoline.

Undoubtedly the greatest waste in running a car is in the unnecessary consumption of gasoline. This not only occurs from bad compression of the motor, from carbon, and faulty carburetion, but especially in the lack of proper vaporization of the fuel. A new appliance for the complete vaporization of the fuel is called the Carburette Vaporizer, and it is claimed it will save 25 per cent. of the gasoline consumption. It also acts as a filter, and of course makes more power and a smoother running car. The price of this appliance is a mere bagatelle compared to its value. It is made by the Perkins Appliance Company, 539 Worthington St., Springfield, Mass.



STARTERS AND LIGHTERS

Glare Protection.

The E. G. Staude Manufacturing Co. of St. Paul, Minn., has placed upon the market something which they call a "Glare Stopper." A good many different kinds of dimmers are already made for headlights, but this device protects the driver. It can be adjusted to any kind of windshield and is easily installed. There is no reason now why a car driver should feel like a blind man from the glare of an approaching automobile, but he can be confident he will not have a collision because of dazzled eyes. It is worth something for a man who drives at night to know exactly where he is going.

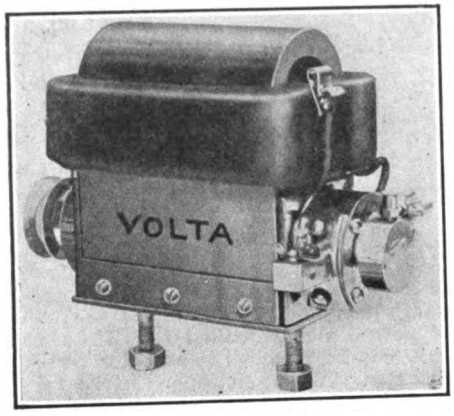
Dimmed by a Kick.

You can now dim your headlight or shift from headlight to sidelight by simply a touch of the left and free foot. The new device is called the Kickover, and it may be attached to any electrically lighted car in conjunction with the regular lighting switch. It is designed for dimming the headlights by throwing them in series but may be used for dimming through resistance or for directing the current from head to side lights or vice versa. It enables you without the slightest inconvenience to change your lights going in and out of cities and to perform the highly appreciated courtesy of dimming or extinguishing your glaring headlights when meeting other cars—meanwhile affording a driving light. It is made by the H. P. B. Electric Company, Inc., 500 Fifth Avenue, New York.

Dimmer Attached to Footboard.

Electric Lighting and Starting.

Ford car owners desiring a splendid electric lighting and starting system that is simple, steady and sure and is sold at a low price, should communicate with the Disco Sales Company, 969 Jefferson Ave., Detroit, Mich. This firm makes starters for all other kinds of cars.



Digitized by Google

A New Starter.

Automobile starters are as thick as "leaves of a Vollombrosa" and some are of undoubted merit. Now one is on the market of which the manufacturers say "it took 90 days to dominate the field." Whether this be so or not this new starter, which is called the Genemotor, is becoming rapidly known and it is unusually compact and has the appearance of being practical and effective. It is made by the General Electric Company, and this is a guarantee that it will do whatever is claimed for it. The agents are A. J. Picard & Co., 1720 Broadway, New York.

Volta Electric Lighting System.

The Irwin D. Groak Engineering Company, Monadnock Block, Chicago, Ill.,

have placed on the market a lighting system which is most economical. The Volta Electric Lighting System is cheap and cannot be surpassed for steadiness, brightness and ease of manipulation. In installing this system of lighting, your gas lamps can be used, as silvered parabolic reflectors, properly wired with sockets can be inserted in the gas headlights and will give good service. These lights are simple in design, no fuses, relays, bucking coils, rheostats, dimmers or other cumbersome paraphernalia to annoy. Everything required is inherent in the generator and the system itself. The care of the Volta system is simple yet it can always be relied upon. Only a few hours time is required to change your old system of lighting into a modern, convenient, safe electric lighting equipment. If your car is wired and you are now using a storage battery, you can simply install a Volta generator. The Ford can be completely equipped for electric lights in about three hours. The Volta is illustrated herewith.

Kemco Starting-Lighting System.

This machine is so designed that it cranks your engine by duplicating the movements made when cranking by hand. When you press the starting button, the same starting clutch you have always used instantly slips into engagement with the crank shaft. When the engine speeds up, the starting clutch is automatically thrown out, whether you release the button or not. The starter puts each cylinder over the compression rapidly. No changes in your car are required in attaching the starter other than removing the crank handle and mounting the starter in place of it. The entire equipment, starter, dynamo, lamps, battery, switches, instruments, wiring, etc., can be installed on your car in a few hours. Those desiring this equipment should address The Kemco Electric Mfg. Co., Cleveland, Ohio, and it is absolutely necessary in ordering to give the year and model of your machine.

For Motor Car Headlights.

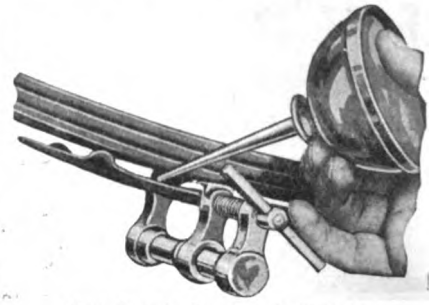
A new appliance for the protection of motor car headlights is called Klearglow, the auto light diffuser. Automobile owners as well as garage men, chauffeurs, accessory dealers, police officials and others cannot fail to see its many advantages. It is designed to eliminate the dangerous glare which causes so many accidents. It does this without cutting down the light, as with dimmers and similar appliances. Pedestrians and motorists approaching your car on the road become half blinded when a glaring light is cast into their faces and cannot see you coming. No motorist can afford to assume these risks. Neither does an automobilist care to be arrested and fined for the violation of the various laws covering automobile headlights. Klearglow is made entirely of glass and can be put on in ten minutes, in place of your present headlight glass. It can remain on permanently for city or country driving, and does not have to be removed in order to get enough light on dark, rough rural roads or dimly lighted city streets. Klearglow is handled by H. G. Paro, 30 North Michigan Boulevard, Chicago, Ill.

The Pres-Toe Starter.

A good many automobile starters need something more than a press of the toe

to make them effective. The one made by W. Robertson Machine and Foundry Company, 32 Greenwood Place, Buffalo, N. Y., does just what is claimed for it. It is designed especially for Ford cars and is simple, effective and of low cost.

One Tree Brings $100.



The Government has received $99.40 in settlement for a single sugar pine tree which was cut in trespass in the Stanislaus National Forest, in California, and which yielded more than enough actual lumber to build a good-sized suburban house. The tree scaled 18,933 board feet and was valued at $5.25 per thousand feet. Not many trees contain enough lumber to build a two-foot board walk nearly two miles long, and this is believed to be the first case on record in which a single tree felled in a National Forest was valued at almost $100 on the stump, although National Forest timber is frequently sold at considerably higher rates.

Subscribe to the "Automobile Dealer and Repairer," $1.00 Per Year.

LUBRICATION

Low Cost Spring Lubricator.

Whether your car is in daily use or in storage, its springs must have attention. If neglected they rust and freeze or adhere to each other. Occasional oiling will prevent this, will lessen breakages and effectually stop all squeaks. It spreads the leaves just enough to insert the lubricant, without marring the paint. The damaging cold chisel and hammer and the jacking up of the car are no longer necessary. The Spring Leaf Lubricator Company, Ann Arbor, Mich., manufacture the Knowlson leaf

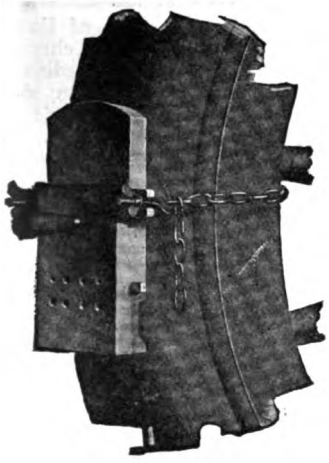
Knowlson's Spring Lubricator.

spreader, and they have so much confidence that it will please users that they will send one, charges prepaid, with the understanding that it may be returned, and the amount paid for same refunded, if it is not entirely satisfactory.

A Novel Grease Cup.

The Klicket Ratchet Grease Cup is replaced free if a cup is ever lost or any parts break. It is made in all sizes and in three styles. The price is nominal, and it will save grease and give a much improved lubrication. In writing for a sample give the inside diameter of the cup, size of the pipe thread required on the bottom of the cup, or the diameter of the bearing hole. The firm also has an attractive dealers' proposition. This grease cup is made by the American Stamping Company, 600 Burchard St., Battle Creek, Mich.

Efficiency Gas Defined.



Efficiency gas is called gas because it goes into gasoline. It really is a lubricant. It has been known to the gas engine world for a long time that, if possible, a great advantage would be obtained by lubricating by way of gasoline. However, this was a difficult thing to accomplish as it was necessary, first, to construct a lubricant that would uniformly expand or mix in a body of gasoline; secondly, it was important to produce a product, a small quantity of which must have a tremendous spreading quality. Another difficulty, the most important, was the fact that this oil must be heat resisting sufficient to live in the combustion chamber of a motor. The molecules of the oil had to be reduced to about the equal size of gasoline. It also had to be an oil that would not gum up the needle valve of a carburetor. But it has finally been accomplished with a product that will thoroughly mix with gasoline without stirring and that can be evaporated with the gases and uniformly introduced into the combustion chamber of a motor.

The continuous use of efficiency gas

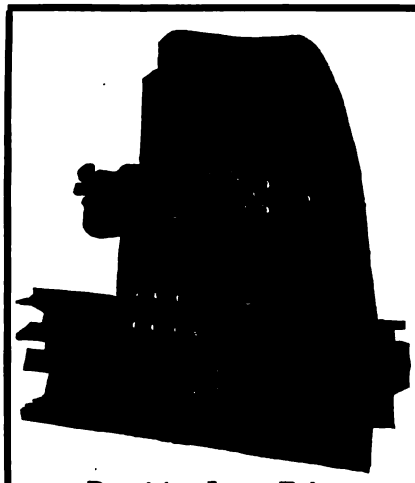
WIZARD AUTOMATIC STEAM VULCANIZER



NEW PRICE ONLY $3.50, BY MAIL PREPAID

Repairing Casing

By manufacturing these vulcanizers in such mammoth quantities we are now able to sell them at only $3.50—you can save this amount in repairing just a few tires.

Don't ruin your casings by neglecting those small cuts—they mean the loss of real dollars to you. Vulcanize them full of new rubber, and MAKE THEM LAST TWICE AS LONG. Ask any tire manufacturer if this is not so. The small cuts admit water and sand to the fabric and the tire soon blows out at this weakened spot.

Repairing Inner Tube

10 DAYS' FREE TRIAL We will ship this vulcanizer by mail prepaid. Try it for ten days and if you are not entirely satisfied, return it, and we will refund your money.

The WIZARD AUTOMATIC STEAM VULCANIZER is adapted for BOTH TUBES AND CASINGS OF ANY SIZE. It is a metal body filled with water at factory and never needs refilling. Steam generated by a small flame which is entirely enclosed. Burns gasoline with a blue flame and no smoke. Heat is automatically controlled. Requires no watching. Vulcanizing face (curved to fit casing) 3 x 6 inches. The Wizard is highly polished and nickel plated. Can be used on the road or anywhere. Pays for itself in a short time and will never wear out. Thousands in use. ANY BOY CAN EASILY OPERATE THE WIZARD. Sent by mail prepaid, upon receipt of the price. Full instructions, rubber, shears, cement, etc., furnished with each outfit. Remember, money back if not entirely satisfied.

PRICE COMPLETE, PREPAID, $3.50

Manufactured by

The National Motor Supply Co.

5636 Euclid Avenue CLEVELAND, OHIO

Branch Office, 2204 Michigan Avenue, Chicago, Ill.

Enclosed find money order for $3.50. Send me by mail prepaid a Wizard Steam Vulcanizer. You agree to refund my money if I am not satisfied after ten days' trial. (Write plainly.)

in gasoline, kerosene and distillates results in an actual economy in fuel of many times its cost and the manufacturers are so confident of its merits that they will refund your money upon the receipt of the empty can and a statement from you to the effect that efficiency gas does not produce the results claimed for it.

Noise Eliminated.

The Badger gear compound made by the Wadhams Oil Company, Milwaukee, Wis., keeps the rear axles and transmissions quiet and is said to be a splendid lubricant. It does not run thin and never packs onto the sides of the gear case. All this is important. Those wanting more information should address the company as stated.

The Klicket Grease Cup.

The manufacturers make a broad guarantee to replace, without charge, any "Klicket" Grease Cup which becomes broken or from which the cap is lost. The simple, durable ratchet device is placed within the cup itself and there are no outside wires or springs to become bent or broken. It can be turned down as easily and accurately in the dark as in the daylight and the operator knows exactly how much grease has been forced into the bearings, as the number

Cut away View.

of "clicks" indicates the number of turns which he has given to the cup. The Klicket Ratchet Grease Cup is made in all sizes, to fit all cars, including the Ford, cycle cars, etc. This grease cup has been manufactured for some time by the American Stamping Company of Battle Creek, Mich.

THE RUNNING GEAR

A Compact Shock Absorber.

There are no wearing parts or friction surfaces on the Flaum shock absorber. It is claimed it will instantly adjust itself to all conditions of either road or load. It requires no oiling and there is no reason why it should not last the lifetime of the car. It is made by the Flaum Shock Absorber Corporation, 173-5 Hudson Street, New York, N. Y.

Tires and Tubes.

The Walsh Tire & Rubber Co., 400-440 Hanover Street, Pottsdam, Pa., is now allotting to jobbers and dealers the sale of their tires and tubes. They are making very liberal dealer discounts and will brand these goods with the name of the dealer if desired. These tires and tubes are said to give the maximum of service at the minimum of price. Application for samples and prices will be given prompt attention by addressing the manufacturers as above.

A New Light Weight Tire Protector.

A new Woodworth Tread has just been placed on the market called the Light Weight Tread, which has many advantages and sells at much lower price. The protector is held on the tires by coil springs, placed about a foot apart along each side and connected by strong, inelastic fabric strips. These are fastened to the leather in such a way that they hug very closely against the sides of the tire. These springs automatically adjust the treads, keeping them always

Woodworth Tread.

perfectly tight so that there is no danger of the tire being chafed and consequently overheated. The tread is made of one ply of leather throughout its width and is studded with from three to six rows of steel-studs on the middle portion, according to the size. The leather is practically puncture-proof; it is permanently water-proofed so that it always remains flexible and as the treads are very light they have no noticeable effect on the power or easy riding qualities of the car. A circular telling all about these treads has just been published and can be obtained by writing to the manufacturers, the Leather Tire Goods Company, Niagara Falls, N. Y.

The Lund Shock Absorber.

This shock absorber is manufactured by H. Lund Smith, Paterson, N. J., and is adapted to any car, being made in

various sizes and can be applied to any shape or form of spring. It is claimed that it will give greater speed to a car because it tends to prevent skidding as well as to eliminate vibration. The firm has received a good many testimonials from well known men in the locality of Paterson, and they offer to send a set of these shock absorbers and allow them to be used ten days. If not perfectly satisfactory and all that is claimed for them, the money will be refunded without question. The illustration gives a good idea of the sturdy construction of this shock absorber.

The Standard Tire Pressure Gauge.

The Twitchell Air Gauge is a good one to use and a good one to sell. It is good to use because it completely answers the purpose and is good to sell, not only for this reason, but because the demand for it is bound to be large. The firm manufacturing it formerly had difficulty in supplying the demand, but they are now in a position to fill orders quickly and they solicit inquiries from those who desire to sell them. The gauge is already in the hands of a good many jobbers, dealers and garages and is made by the Twitchell Gauge Company, 1213 Michigan Ave., Chicago.

A New Tire Tread.

The Armor Tread Company, of Hartford, Conn., make a tire tread of chrome tanned leather to slip over the ordinary rubber tire casing. It prevents rim cuts and blowouts and is said to add to the appearance of a car as well as to prolong the life of the tires. There is not the slightest doubt concerning this last named claim for the leather is unusually tough and strong and these treads can be used on well worn old casings if the fabric is in a fairly good condition. They are made in all sizes and for all models of cars.

A Rim Contractor.

There is being made and rapidly put on the market a tool that does not touch

the tire, but opens the rim lock and will permit the immediate removal and replacement of tires in an upright position. There is nothing to adjust. Its weight is practically nominal and it will fit into the tool box. It removes the rims instantly and is on the whole a decidedly labor-saving invention. It is made by the Friestedt Rim Contractor Company, 2931 West Lake St., Chicago.

The New Differential.

Technical writers and automobile engineers have long acknowledged the drawbacks of gear differentials, but since differential action is considered essential to a motor car, the disadvantages have been accepted as necessary evils. There is now, however, upon the market a device which seems to have overcome the difficulties experienced with former substitutes for the gear differential. This is the latest development of the Gearless Differential Company, Detroit, Mich. The new mechanism takes the place of the gear differential at the center of the rear axle,

and in the case of the model "T" size can be substituted in a Ford rear axle without in any way altering the axle housing, ring gear, shafts or bearings.

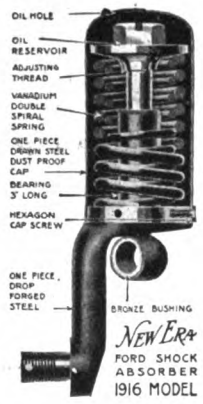
The claims of superiority over the gear differential are numerous, and are substantiated by the testimony of many prominent users, who say that this device does all that is claimed for it. Some strong claims are made for this device, as to its strength and efficiency, over the differential gear. A positive drive to both rear wheels is transmitted, therefore one rear wheel cannot spin on a slippery surface, and the other stand still. Dangerous skids are eliminated, and a Ford car has a positive service brake on both rear wheels, regardless of road conditions. There being no sideway at high speed, the danger of overturning is great diminished. A saving of fuel and tires is effected by absence of slipping, acceleration when one wheel is thrown from the ground, and tendency of back wheels to get out of line (using power to bring them back), also the driving on the wheel traveling the shortest distance, all mean less revolutions of the motor, thus an actual saving in fuel, and wear on tires.

Tire Pump and Crank Combined.

This is a new device made to replace the starting crank furnished with the car, providing a quick and convenient method of inflating tires. The pump is inside of the crank and to use it for inflating tires requires only the forward movement of one nut with the thumb and finger after attaching tube. It can be installed on a Ford car in about one hour, no machine work of any kind being necessary.

In the manufacture of this pump only fine materials are used and each part is made with mechanical precision. The piston and piston rings are ground to the exact size of the cylinders, cylinders are lapped to a glass finish. All bearings

Tire Pump and Crank.



are made of phosphor bronze and the crank shaft of high carbon steel, tempered in oil. No leather washers are used. Each pump is furnished with hose and pressure gauge and the complete device is fully guaranteed for one year. The DeLaunty is manufactured by the Chicago Automatic Machine Company, Oakley Ave. and Kinzie St., Chicago, Ill.

Don't Be Wasteful.

There is probably more money wasted on tires than in any other part of the automobile. Worn shoes are thrown away as if they had no value whatever, and thus tire service costs about twice as much as it should. Well-worn tires may be retreaded with Pacific Fibre Treads and thus they will have an additional service, in some cases as great as new tires. They expand or contract easily and thus are sure to fit. Another thing that is surely attractive is the fact that the manufacturer will ship them on approval, pay express and take all the risk. When tire expense can be cut from $50 to $500 a year it pays to give the subject a little thought and attention and to use any saving device that is practical and bids fair to do all that is claimed for it.

New Era Shock Absorber.

The New Era Elliptic Shock Absorber, illustrated herewith, for light, medium and heavyweight cars, will appeal to the vast number of owners needing more comfort and at the same time save the car from excessive shock. The New Era gives great resiliency and absorption of constant vibration from small de-

pressions of the road. The best material obtainable is used in the construction of these shock absorbers and they are permanently guaranteed against defects. These shock absorbers are especially designed for Ford cars and more complete information regarding them will be furnished by the manufacturers, the New Era Spring and Specialty Company, 864-878 Woodward Ave., Detroit, Mich.

Yankee Folding Tire Pump.

The Yankee folding tire pump is clamped, when not in use, to the running-board of the car, so that it is not necessary to use any energy in holding it while pumping, and the user stands in a natural, upright position, working a long lever. When not in use the pump is doubled up and goes easily into the tool box. The device is manufactured by the Eugene Atkins Co., Elkhart, Ind.

A Tire Pump and Crank.

These useful devices are combined in what is called the DeLaunty Tire Pump and Crank. It will be sent on 30 days' trial and is made by the Chicago Automatic Machine Company, Oakley Ave. and Kinzie St., Chicago.

The Right Shock Absorber.

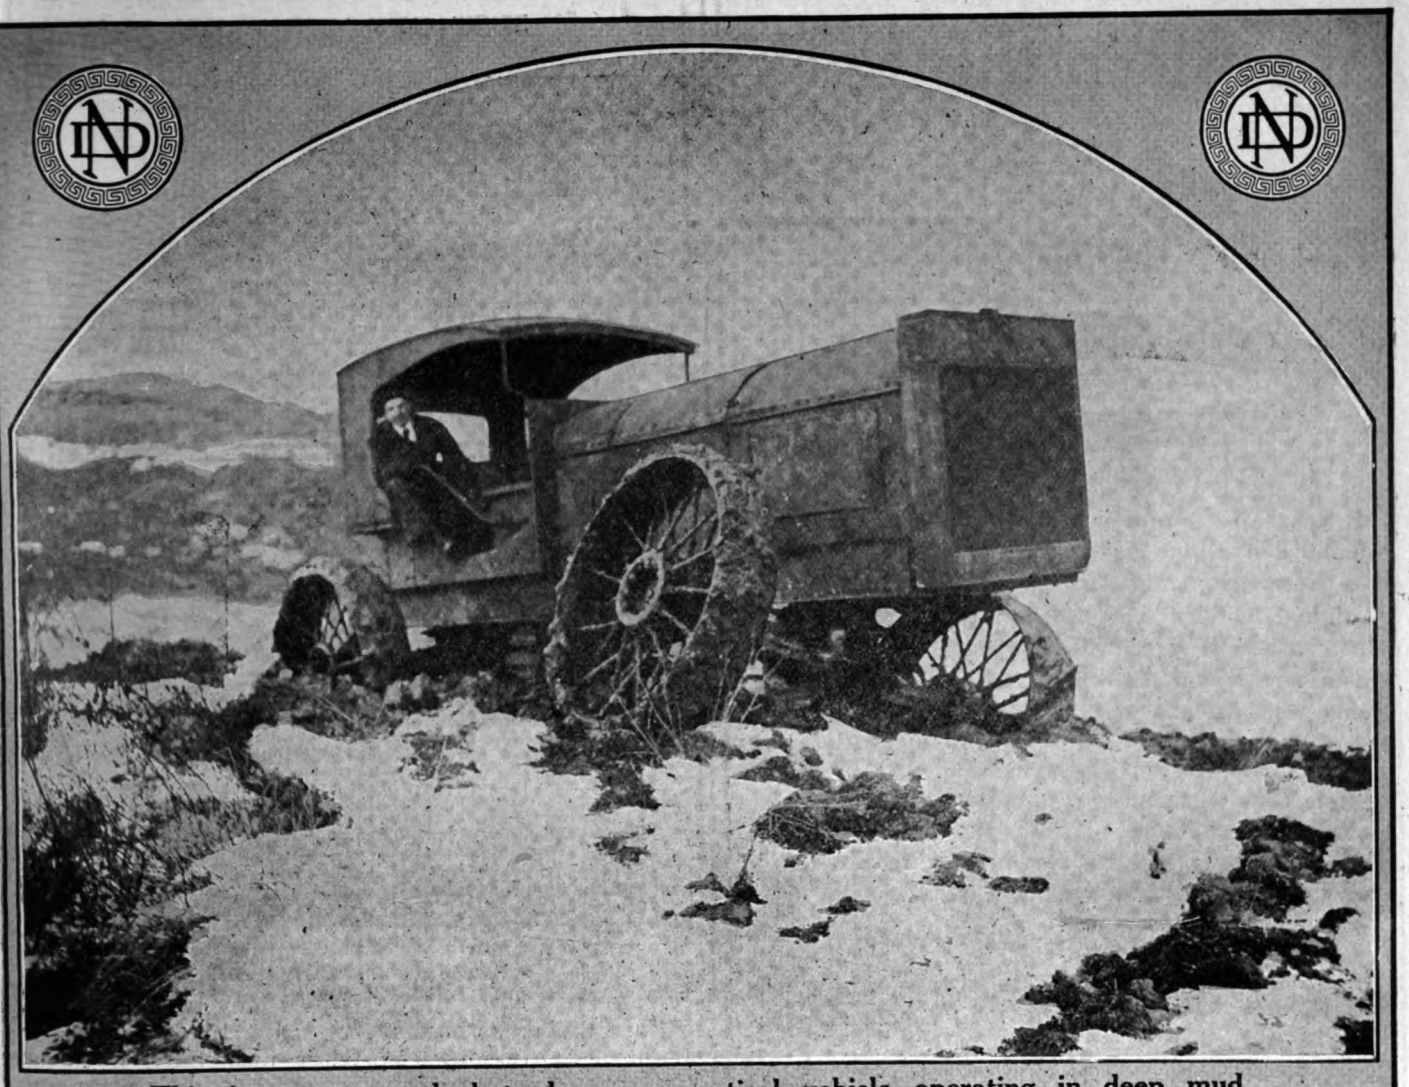
A special shock absorber for the cars from 1,800 to 3,200 pounds in weight has been put on the market under the trade name of the "Right" Shock Absorber. It is designed especially to meet the requirements of medium weight cars and has a resilient action of two inches. It is capable of absorbing even the most violent road shocks. The strain of the shock is reduced to a minimum, with a consequent saving of tires and the whole car. Periodic swaying of the main springs at high speed is absolutely eliminated. All wearing parts are provided with bushings, which can be replaced at slight cost. The list price of

Unusual Resilient Action.

the Right Shock Absorber is very low, and special care has been taken to make it an easy proposition for the dealer and jobber to handle. It is manufactured by the Right Motor Specialties Company, 1320 Michigan Ave., Chicago, Ill.

More-Room Steering Wheel.

By the use of the More-Room steering wheel, illustrated herewith, getting in and out of the car is easier and stout people will not find it necessary to squeeze into the driver's seat. It is said to give eight inches more room than with the ordinary steering wheel. This steering wheel can be attached in fifteen minutes and is two inches larger than the regular Ford steering wheel. The illustration will give some idea of



Extra Room Shown

its appearance. It is fitted with a corrugated rim to insure a good grip and is machined to fit the regular steering column of the Ford car. It is made by the Neville More-Room Steering Wheel Company, 714 David Whitney Building, Detroit, Mich. The wheel is furnished with ebony finish solid rim and polished aluminum spider.

It's All in the Lock Joint

If years of compression practice have taught the motor and engine makers that a piston ring should be **Eccentric** and not concentric—and that the original foundry scale of the metal should *not* be removed from the inside of the ring, why should a motor or engine owner install another type of ring when he can get the **Peerless Piston Ring?**

A one-piece, eccentric piston ring that is absolutely compression tight and carbon proof.

Its lock joint is integral with the ring—no loose pieces to drop out—no multiple parts.

The Peerless is an eccentric, one-piece ring, made from close-grain gray iron—the type of ring which years of compression practice with steam and gas has proved best.

Its opening is sealed by the patented Peerless Lock Joint—and compression leakage is impossible.

Peerless rings are accurately made with the original foundry scale of the metal left on the inside. This means strength and flexibility.

They are **Eccentric,** which allows a uniform pressure on every point of their periphery.

The Peerless is easier to install than any multiple-piece ring—easier to carry in stock because rings never become separated—easier to sell because they are sold on a money-back guarantee.

Deliveries can be made at once in any quantity, in standard sizes. Prices will interest you. Write us about them today.

Cheap Pressure System.

From E. W. T., California.—It may be of interest to Ford owners who have occasion to drive in the mountains, to know that they may have a valve stem from an inner tube inserted in the filler cap of the gasoline tank, thereby having an inexpensive pressure system which will enable them to ascend grades which they could not do with a gravity feed. Drill a hole in the filler cap, insert the valve stem (one from a motorcycle tube is better being smaller) put on gaskets above and below and washers and nuts to make it air tight. A piece of string packing or a waxed cord around the filler cap next to the tank will stop the leaks there. A stroke or two of the pump attached to this contrivance and you can climb "straight up." Be careful and not put too much pressure on the tank, a very little will be sufficient.

Pumping the Tire.

Before starting to pump air into a tire which needs more pressure, it is a good plan to insert a piece of iron or copper wire into the valve and depress the plunger. If air has not been pumped in for some time, the rubber end of the plunger is apt to stick to the seating. If it is not first loosened by direct pressure, the result is that such great pressure is put on the pump connection that it may burst and the pump connection be rendered useless or at least faulty. If there be a gauge on the pump, this, too, will probably be strained badly. Possibly this is a well known "tip," but many beginners do not know of it.

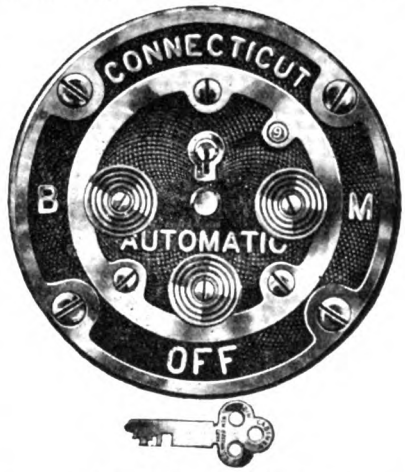
Utility Tools with Flexible Shafts.



In meeting special orders for motor-driven tools equipped with flexible shafts for use in die sinking, grinding, buffing, polishing, etc., the Stow Manufacturing Company, Binghamton, N. Y., has developed a number of electric tools of great utility, two of which are illustrated herewith. It shows a tool which is especially applicable where a wide range of flexibility and speed is desired. It consists of an adjustable standard upon which is pivoted the main rod having at one end a Stow flexible shaft and at the other end a motor, the latter serving both as power unit and counterweight. By means of the countershaft and pulleys three of the latter being interchangeable, a range of speed between 400 and 7,000 revolutions per minute can be obtained, thus making the machine suitable for drilling in wood or steel and similar work. The tool can also be dismounted from the standard, and suspended from the ceiling, similar to the Stow suspended-type direct-connected tool shown. When one speed alone is desired for grinding or buffing, or light drilling, the suspended type without countershaft is recommended. This tool is very serviceable in assembling work, since it has a large radius of action and can be mounted over the work so as to be out of the way and yet quickly accessible. Both these tools are made for 110 or 220 volts direct current and for similar voltages on 60-cycle single-phase current.

Two Labor-saving Devices.

A Novel Automobile Lock.

The Connecticut Telephone and Electric Company have just placed on the market a new type of lock as applied to their automatic switch controlling their automatic igniter system. This lock is different from the ordinary ignition lock inasmuch as the key is required only to unlock it, the switch being locked by means of a small plunger directly over the right hand button. With this arrangement it is possible to carry the ignition key on a bunch as it is not necessary to leave it in the lock when the car is being used. In order to operate the locking feature, it is simply necessary to press the small button after the switch button has been released and the ignition shut off. It is so designed that it is not possible to lock the ignition until it has been thrown off. It is simple in construction and fool-proof. The keys are not interchangeable as is the case with most ignition locks, which is a decided advantage as it is not possible to unlock it with one common key which largely destroys the effectiveness of a lock of this nature.

The Lock and Key.

Increase of Reos.

March production figures issued by General Manager R. H. Scott of the Reo Motor Car Company, of Lansing, Mich., show a 50 per cent. increase in business over March, 1914. Last year in March the Reo turned out 1,792 pleasure cars, while this year's March production aggregated 2,589 cars.

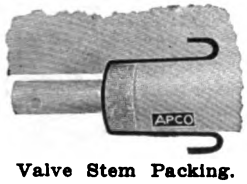
Known bondholders, mortgagees and other security holders, holding 1 per cent. or more of total amount of bonds, mortgages or other securities: No bondholders, mortgagees or other security holders.

MOTOR VEHICLE PUBLISHING COMPANY,
F. R. WHITTEN, Secretary.

Sworn to and subscribed before me this 30th day of March, 1915.

[L. s.] (Signed) HARRY F. REISS,
Notary Public, No. 72.
(My commission expires March 30th, 1917.)

devices while four different types of Apco anti-rattlers come with the third stand.



This firm has also perfected a device for overcoming the troubles experienced with worn valve stems and guides which allow air to be drawn in on the intake stroke, diluting the mixture. Much of

Anti-Rattler.

the missing at low motor speed and starting troubles are due to this condition.

The Apco valve stem packing consists of a steel stamping carrying a felt washer. The washer is pressed against the bottom of the guide and stem and is held in place by the spring. The device can be attached without tools, and one of its desirable qualities is that it

Valve Stem Packing.

keeps out abrasive elements. As the felt is oiled the stem and guide are lubricated, increasing their life. The packings come eight to the set, four being used on the intake and the balance on the exhaust. When fitted to the exhaust they eliminate the hissing noise caused by the gases escaping on the exhaust stroke. The Apco valve stem packings are sold with the Apco unqualified guarantee of "satisfaction or your money back."

Gasoline for Kerosene.

Thinking she had the kerosene can, Mrs. J. M. Lightner, of Hickman Mills, Mo., south of Kansas City, Mo., poured some on a smouldering fire. The can contained gasoline and exploded with terrific force, burning her so badly that she died a few days later after great suffering. A husband and five little ones mourn her loss.

C-C SHOCK ABSORBER

Why you should sell this Shock Absorber

1st. They satisfy the customer. There are thousands of C-Cs in use today and every one is making good.

2nd. They are a quality product. All working parts are of special heat treated steel made to stand abuse. Incorporated in the C-Cs are mechanically correct features that make for efficient shock absorption.

3rd. The price is right. At $10.00 set of two, complete for the rear, the C-Cs will be attached to hundreds of automobiles in your vicinity. It is only due to enormous production that this exceptionally low price is possible.

4th. The profit for you is big because of the demand which has been created through the extensive advertising we have been doing.

Are you going to take advantage of the results of the thousands of dollars that are being spent to advertise C-Cs?

FORD MODEL $8.00 Set of Four—$4.50 Set of Two

Thousands in use today with exceptional results in comfort and reduction of upkeep expense.

Write for dealer's proposition.

Life of Horses on the Firing Line.

That the average life of a horse on the firing line in France is about ten days was the astonishing declaration of a British army officer identified with the remount department. Horsemen were prepared to hear of unexampled wastage after reading about the havoc wrought by modern artillery and machine guns, but this report indicates such slaughter as had not been dreamed of in this country. In the civil war in this country the wastage of horses was at the rate of about 500 a day in the Union army, and the service of a cavalry horse under an active commander then averaged about four months. During his Shenandoah Valley campaign Sheridan required 150 fresh horses a day, and in eight months the cavalry of the Army of the Potomac was remounted twice, nearly 40,000 horses having been required. If the British officer's estimate of the wastage is not wide of the mark, it is a foregone conclusion that before the carnage ends there will be such a shortage of horses as Europe has never seen. As most of the animals now in the field were commandeered from farmers and others who had been using them in agriculture and industry, and this demand, added to that of the war, will, it is believed, seriously affect the price of horses the world over during the next few years.

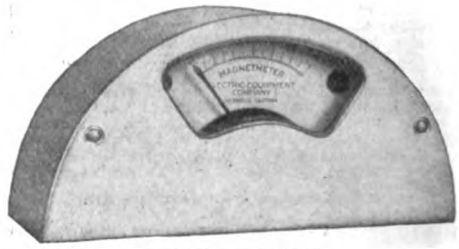
ECO MAGNET CHARGING AND TESTING OUTFIT



MAGNET CHARGER

The CHARGER operates on either a six volt Storage Battery or five dry cells, and is Guaranteed to charge all magnets to saturation point. The Charger is adjustable to magneto magnets of different sizes and curvature. Maximum results are obtained instantly.

It is a profit producer for any Repairman.

The MAGNETMETER or Tester shows definitely and positively the condition of the magnets and whether they have been properly charged.

MAGNETMETER

By the use of this outfit any Repairman can correct and repair difficult cases of Ignition trouble resulting from weak magnets.

WRITE FOR PRICES AND BOOKLETS.

LE MUNYON & BIDELMAN, 521 Black Building, Los Angeles, Cal.

BUSINESS READING

The business man should be a constant student of the thing in which he has invested his capital, his experience and his effort. To do this he must acquire the reading habit. If he neglects this he makes a costly mistake.

The man who imagines he is too busy to read should never go into business. The chances for his failure are too great, and at best his success can never be more than a half-success.

There is no better business reading than the advertisements in this number. They are full of information and no one who is interested in automobiles can afford to neglect them.

A New Axle Brace.

The M-G front axle brace and shock absorber for Ford cars it is claimed will not only prevent bending or breaking of the radius rod, but makes the car steer and ride better. It is sold under a money back guarantee and is manufactured by the Monnich-Gaylord Co., Hooper, Neb.

Circular Screwdriver.

Hess & Son, 1031 Chestnut St., Philadelphia, are placing on the market what is styled a pocket-piece screwdriver. It is made of steel, is circular in form, about the size of a quarter, and may be carried on a key ring. The outer edge increases in thickness around the circumference, so that the device will fit all sizes of screws.

A Big Chain Drive.

The largest chain drive in existence, three times greater in size than any previously built, is to be found at the Ox Bow Power Plant, on Snake River, Copperfield, Oregon. The plant consists of a 3,600 kilowatt generator, operated by two water-wheel units, each consisting of two pairs of waterwheels of the 48-inch horizontal type, operating under a 21-foot head. The speed of the waterwheels is 147 revolutions per minute, and each water-wheel unit is connected to the generator by four Morse chains, each 21 inches wide, the sprockets on the line shafting having a 2-inch pitch, and the shaft centers being 10 feet apart.

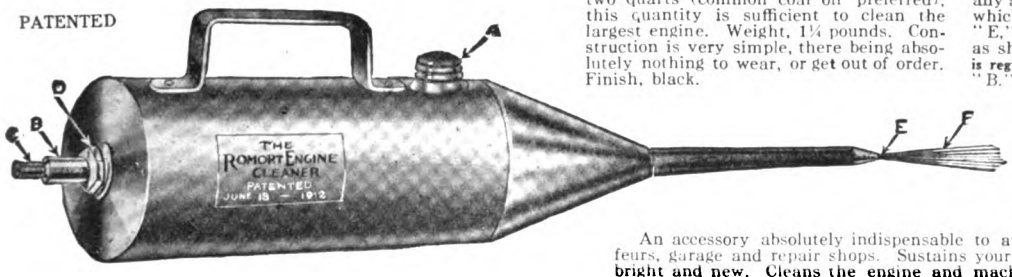
One Dozen Rubbers to a Carton **Price 25 Cents per Carton**



A scientific Romort design, made of a Special Compound of Rubber (not dope), has the best wearing qualities. Easily slips on the tire valve, **Will hold fast and will not turn inside out. Don't be misled by cheap inferior washers similar to Romort design—Genuine Romort Rubbers are stamped "Romort."** Leading Jobbers and dealers carry **Romort Rubbers** in stock—if yours don't, fill out Coupon below.

The Romort Engine Cleaner

PRICE $3.00 Each

PATENTED

DESCRIPTION

The Romort Engine Cleaner is 20½ inches long by 4 inches in diameter, a convenient size for carrying in a car. Fluid capacity, two quarts (common coal oil preferred); this quantity is sufficient to clean the largest engine. Weight, 1¼ pounds. Construction is very simple, there being absolutely nothing to wear, or get out of order. Finish, black.

HOW TO OPERATE

Fill the tank as shown in the cut at letter "A," attach the cleaner to hose or air supply at letter "C," (standard connection will fit any air hose). Turn knurled rod at letter "B," which opens valve and lets fluid out at letter "E," fluid is forced out in a very strong spray, as shown by letter "F." **Light or heavy spray is regulated** by a slight turning of knurled rod "B." The packing nut, as designated by letter "D," may be easily detached and repacked if found necessary.

NO DANGER OF EXPLODING

As the air does not enter the tank, but passes right through, picking up the fluid at letter "E," there is absolutely no danger of the tank blowing up—this being impossible.

An accessory absolutely indispensable to automobile and motorcycle owners, chauffeurs, garage and repair shops. Sustains your car efficiency by keeping the machinery bright and new. Cleans the engine and machinery perfectly without the use of rags, **waste or brush. Designed for the special purpose of cleaning automobile and motorcycle engines and machinery, it is constructed with a long spout or point, so the operator may easily reach every nook and part of the machinery, an impossibility with the old method of rags and waste. The dirt and grease readily disappear before a strong spray, which works under a very low air pressure. Use an engine-driven or spark plug pump, garage storage systems or in fact any air pressure system from 10 pounds to 200 pounds. It cleans the machinery of your automobile or motorcycle just as readily and with the same result as one would hose off the outside of the car. The Romort Engine Cleaner, one quart of coal oil and five minutes of your time will do the work.**

For sale by all up to the minute Dealers or order direct - See Coupon attached.

1912-13-14 Ford car equipped with Livingston pointed front radiator and No. 1 streamline hood.

1915 cowl dash Ford car equipped with a Livingston V type radiator and No. 2 streamline hood.

1915 cowl dash Ford car equipped with a Livingston straight front radiator and No. 2 streamline hood.

Immediate Delivery

Livingston radiators are guaranteed to cool the Ford motor under any and all conditions.

Livingston hoods give the long streamline effect so much admired in cars of higher cost. Both add to the style of your Ford car by giving it longer lines, added beauty and individuality.

Livingston streamline Hoods are made in two types:

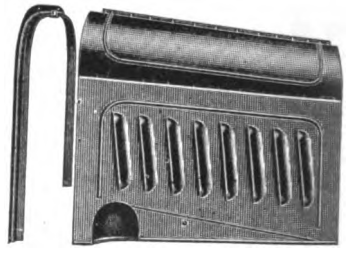
Type No. 1—Fits all Ford cars built in 1912-13-14 and up to February, 1915, and with this hood a "hood ledge" for the dash is included.

Type No. 2—Fits the new 1915 cowl dash Ford car. This hood fits around the curved cowl dash, and a "hood lug" for the top of the curved dash is included.

The 1915 car with the Livingston No. 2 hood attached, gives a perfect **streamline** from the top of the cowl dash to the front of the radiator.

Either hood is waterproof, preventing the water from reaching the motor.

The four "hood hooks" standard on the Ford car are used without changing their position.



Either hood can be used with Livingston radiators or with the standard Ford radiator, and anyone who can handle a screwdriver can readily change hoods in fifteen minutes.

Pointed Front, $40.00
Including Extended Starting Crank.
German Silver, $5.00 Extra.
Water Capacity, 4½ Gals. Weight, 40 Lbs.
Shipping Weight, about 80 Lbs.

Straight Front, $35.00
German Silver, $5.00 Extra
Water Capacity, 2¾ Gals. Weight, 35 Lbs.

America's Pioneer Power Tire Pump

Send for Illustrated Pamphlet

Try One On Your Car For 30 Days

Send for Illustrated Pamphlet

Make Tire Pumping a P-L-E-A-S-U-R-E

There's a way to enjoy this summer's heat when a tire "goes flat." There's a way to laugh in the face of the hot sun, and make tire pumping—

A Recreation

—a chance for a quiet smoke, while a MAYO Spark Plug Pump and your motor, do the work.

MAYO SPARK PLUG PUMP

An Economy

—you can't afford to overlook. It costs much less than one ruined casing—and it can save many—while taking the place of backache-producing hand pump tussles.

The MAYO comes complete—**For $10**

—equipped with 12 ft. hose, gauge, and all connections. Pumps fresh, pure air only. Adapted to any car. Substituted instantly for any spark plug. Built with metal rings, like your motor—and lasts as long. You can test a MAYO—

On 30 Day Free Trial

$10

on your own car. MAYO Q. D. Spark Plug, $1.50 extra; MAYO Ford Pump, $8, complete; MAYO valve cap pump for permanent attachment to motor, $15, complete.

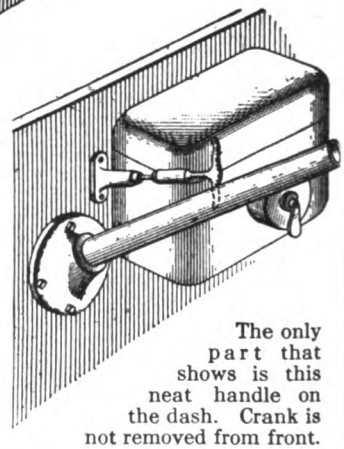
$10

Think of it!

A SELF STARTER FOR 10 DOLLARS

The HUNTER



JUST WHAT THE FORD OWNER HAS BEEN LOOKING FOR

Complete with all attachments and instructions

At Last Mr. Ford Owner!

Your wish has come true. The best starter for a Ford car ever devised and costs less money. It gives you every convenience of the bigger, costlier cars (as you can use electric headlights on your magneto current).

INSTALLED IN ONE HOUR BY ANYONE

The only part that shows is this neat handle on the dash. Crank is not removed from front.

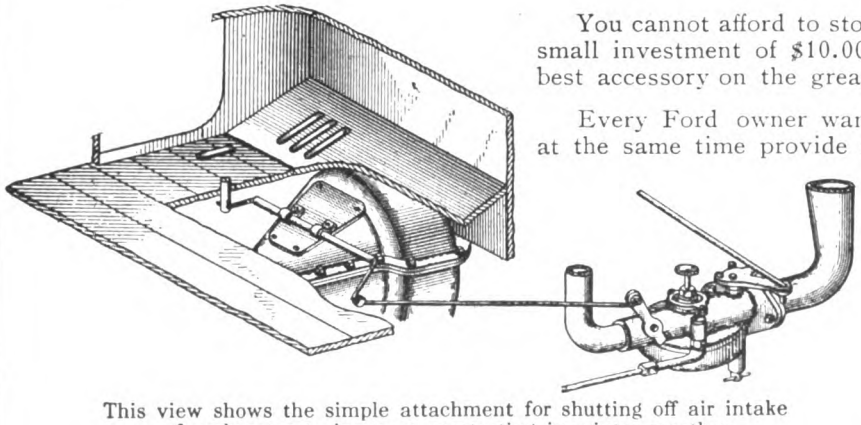
INCREASES THE VALUE OF A FORD THREE TIMES

Note the Advantages

Powerful—The straight pull and powerful leverage enable a woman or girl to start it.

Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.



Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.

You cannot afford to stop at the small investment of $10.00 for the best accessory on the greatest automobile on the market.

Every Ford owner wants to make his car up-to-date and at the same time provide for comfort.

This view shows the simple attachment for shutting off air intake of carburetor to insure easy starting in winter weather.

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. Big money for you in this—the lowest priced reliable Ford Starter made.

HUNTER LOCKS for FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. Price, $1.00. Quickly installed. Sold by leading dealers.

A POSITIVE GUARANTY

THE STRONGEST EVER MADE

Guaranty

Every part of the Hoosier Tandem guaranteed absolutely for one year. This includes the contact points. Any necessary replacements will be made, free of charge, at the factory, the user paying simply the transportation charges.

HOOSIER TANDEM MASTER VIBRATOR

Dealers and Jobbers can now assure their customers of continuous satisfaction.

The Only Vibrator Which Cannot Stall The Car By Sticking.

The Hoosier Tandem has TWO PAIRS OF CONTACT POINTS—instead of one, as have all other vibrators.

Sticking points have always been the cause of vibrator troubles—of vibrator-equipped Ford cars stalling.

The heat produced by the sparking of the points is what makes single-point vibrators stick.

It's the tandem points that make the Hoosier different.

No other vibrator has them.

The kick switch has a removable key, preventing tampering with the car.

The case is solid mahogany, highly polished, 7 inches high, 4 inches wide and 3 inches deep.

The Hoosier Tandem points cannot heat to the sticking point—because they alternate the work of sparking. Neither operates long enough at a time to make sticking possible. The two sets of points are constantly automatically relieving each other under service.

Write us now, today, about your 1915 vibrator requirements. We have a proposition that means more vibrator sales and bigger profits to jobber, dealer and garageman.

If you dealer does not carry the Hoosier Tandem in stock, MR. FORD OWNER, order one direct from the factory. We guarantee it to you on a "money back" basis.

Champion

"TOLEDO MADE FOR THE WHOLE WORLD'S TRADE"

What We Do

For Manufacturer, For Dealer, For Car Owner

For all three we make spark plugs that do the work and stand up under it.

We furnish Manufacturers with over 80% of all the spark plugs which goes into new American Made Motor Cars.

We furnish Car Owners with new Champions of identical efficiency, with which to replace the original Champions grown old in service.

We furnish dealers with a line of Spark Plugs unmatched for completeness.

We create and maintain for our product an insistent consumer demand by continuous, heavy advertising which is truly National in its scope.

We divide our profits with Dealers on an equitable basis in accordance with the service they render to us and to our consuming public.

And above all, by modern methods of quantity manufacturing, we keep the quality up and the costs and prices down.

A Special Word to Dealers

The only Spark Plugs on which the car owner is *already sold* is the Champion.

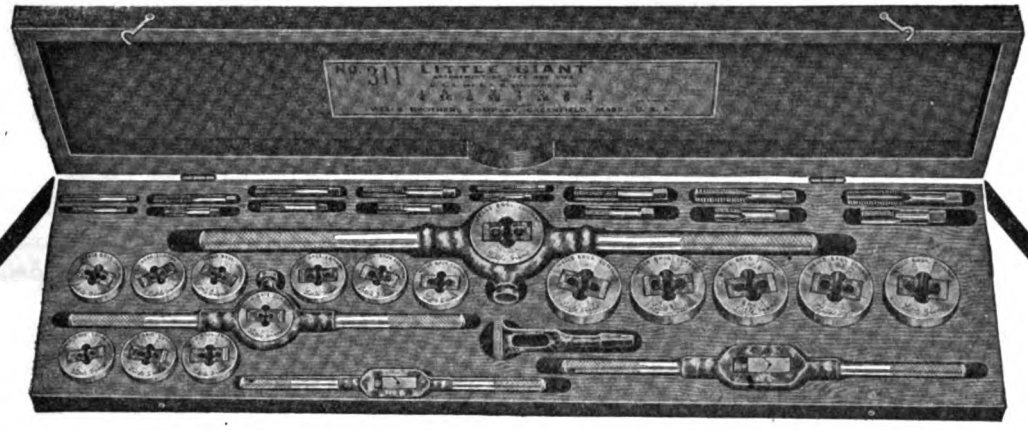
No customer ever yet refused to accept Champions—while most of them demand Champions.

If you keep your spark plug stock a clean Champion stock, there isn't a dead-piece or a sales-task in it.

If you ever have any complaint about a Champion Plug, settle it on the spot. Here's

Our Guarantee

We guarantee complete satisfaction to the user—free repair, replacement or money back.



If we have not sent you our Profit Sharing Agreement, write for it today.

Little Giant **AUTOMOBILE SCREW PLATES**

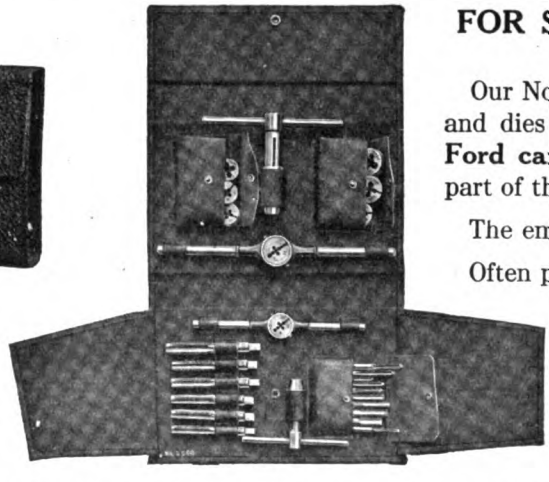
GOOD WORK REQUIRES GOOD TOOLS

Now that the overhauling season is at full blast repairmen and garage owners need tools for cutting screw threads by hand and should have the best. Out of our large and varied list of assortments of taps and dies we want particularly to call your attention to the screw plates, one of which is illustrated above, called

Little Giant **COMBINATION ASSORTMENTS** (Containing both S. A. E. and United States Standard Threads.)

These assortments avoid the expense of buying a separate outfit for each thread standard and the expense of duplication of stocks and tap wrenches.

Little Giant **DIES CUT EASIER** Little Giant **DIES ARE MORE DURABLE**



Impossible for them to tilt or get out of alignment. Increasing the working strain only tightens the grip of the collect upon the working parts of the dies. Send for circular, "Tools for the Automobile." A postal brings it.

WELLS BROTHERS COMPANY DIVISION

LIGHTNING **EMERGENCY REPAIR KIT**

FOR SCREW THREADS

Our No. 2500 assortment of taps and dies is designed especially for **Ford cars,** is equally useful as a part of the equipment of any car.

The embodiment of utility.

Often pays for itself on one job.

Genuine Goat Skin Leather, Canvas Lined Hardwood Case if desired

LIGHT, COMPACT DURABLE CONVENIENT

Has 16 taps, 16 dies, 2 stocks and 2 tap wrenches

Dealers will find a great demand for these sets and we are looking for live agents in every territory to handle them. Write for proposition today.

A BUSINESS FOR $42

Profits from the Trial Period will pay for it

FREE TRIAL OFFER

If at the end of two weeks' trial in your shop, you decide you do not want the outfit, ship it back to us and we will refund your money IN FULL. No strings to this offer. Not necessary to give any reasons.

COMPLETE WATERHOUSE WELDING OUTFIT $42

Waterhouse Outfit

	Value
1 B Welding Torch with 5 tips	$17.00
1 Oxygen Reducing Valve with 50 lb. line pressure gauge	10.25
1 Acetylene Reducing Valve with 50 lb. line pressure gauge	11.00
1 Set of Special Welding Hose (20 ft.)	3.00
1 Pair of Welding Glasses	.75
1 Carbon Burning Torch	Free
1 Set Instructions	Free
Net Cost Complete - - -	**$42.00**

Rods and Fluxes $4.50

What you get

1 Bottle Aluminum Flux
1 Can Cast Iron Flux
1 Can Copper and Brass Flux
2 Pounds Brass Welding Rods
5 Pounds Cast Iron Welding Rods
2 Pounds Aluminum Welding Rods
2 Pounds of Steel Welding Rods.

With a Waterhouse Welding Outfit, you can do work that no other concern can do unless it has a Waterhouse Welding Outfit. Can be efficiently operated by any intelligent mechanic.

Economy of time, metal, labor and machine and hand work after the welding process.

No aditional space or equipment is required. Needs but a small space to successfully operate on the largest work. Can be placed in a corner or carried anywhere.

Economical because there is no waste of time or fuel—the torch will not flash—it can be used all the time it is needed, absolutely safe.

With every Waterhouse Welding Outfit is given a free carbon-burning torch with which carbon can be removed from the cylinders of any car—an incidental but a substantial source of profit.

If you have a regulator for carbon burning, the oxygen regulator usually sent with the outfit is unnecessary, and a deduction of the price ($10.25) can be made from the price of the outfit quoted.

TERMS: 5% cash discount with order or C. O. D., or $20 cash with order, balance in two payments, first of $12 in 30 days, $10 in 60 days after receipt of outfit by you.

Practical instructions furnished free with every Waterhouse Outfit. These instructions deal with the treatment and repair of all kinds of metal. Be the first owner of a Waterhouse Welding Outfit in your community.

If you do not have at your service a welding shop, we will undertake to make repairs and restoration for prices that will be much less than the cost of new parts.

10,000 MILES GUARANTEE BACKS THIS TIRE

TRY Brictson Pneumatic Tires at our expense. Don't pay until you are satisfied. At our risk find out for yourself what wonderful service Brictson Tires give—how resilient and easy riding they are. Get rid of punctures, blowouts and rim cuts. Brictson Tires are rut proof, oil proof and gasoline proof. They are sold under a specific 10,000 mile written service guarantee.

Read What One User Says

"Several months before beginning my trip from Detroit, Mich., to Detroit, Fla., I thoroughly investigated tires of several well advertised kinds. I finally decided for my trip that the Brictson was the most economical and durable tire that I could find.

I am daily asked if I have many punctures. I reply that I do not know what a puncture is. I am driving on all kinds of roads under all kinds of conditions and never have a thing to worry about.

I have been on the road since the 8th day of last October, and if all goes well will begin my Florida trip again about October 1st next. I consider the tires worth almost their weight in gold. I would not do without them at twice the price.

W. J. BREWSTER,
August 10, 1914. 236 Jefferson Avenue, Detroit, Mich."

Your Tires Rebuilt the Brictson Way

If the fabric in the tires you are now using is in good condition, we can take them, make them proof against rim-cutting, punctures, blowouts, side-wall breaks, skidding, ruts, oil, and give thousands of miles of additional service.

Sign and send back coupon for full information and details of our liberal Free Trial Plan.

$48.00 Will Earn $100.00

in three months if invested in a

WEAVER Garage Press

HUNDREDS of these Presses in Garage service have more than paid for themselves in thirty days—so why should YOU continue to throw money away by depriving yourself of this money-making equipment?

Every time you use a sledge to straighten an axle or shaft,—to force a gear or ball race or hub, you lose money in labor and time, to say nothing of the parts which you injure and are compelled to replace.

LEVERAGE 1500 to 1

The lever construction on this Press provides a leverage of over 1500 to 1, so that one man can develop a pressure of 20-tons with very little effort.

DESIGNED FOR GARAGE WORK

Crank shafts and similar bulky pieces can be very readily handled with this Press by reason of the divided bolster, as shown herewith. The bolster may also be adjusted to the extreme bottom of the frame, giving a capacity of 48 inches between it and the screw.

The frame of the Press is 32 inches in width, allowing it to receive the largest automobile wheels for pressing out hubs, bearings, etc.

VISE-BLOCK ATTACHMENT

A "vise-block" is provided which operates between the screw and bolster for the purpose of holding axles, shafts, etc., against a twisting strain.

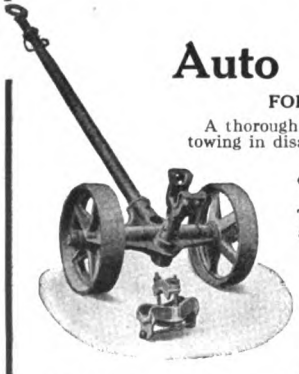
CONSTRUCTION

The frame is one piece of heavy channel steel; the hand wheel is 15 inches in diameter and the weight of the wheel and screw is carried upon ball bearings. The hand lever has a leverage of over 1500 to 1. The thrust of the screws is directed against heavy Bronze Thrust Bearings. The screw is 2 inches in diameter with 3-pitch Acme thread, and has a range of movement of 12 inches. **The Screw Does Not Revolve.**

The bolster which carries the plate can be set at any desired height with extreme adjustment of 48 inches. The width between frame uprights is 32 inches, height 74 inches, floor space 36x36 inches, weight 425 pounds.

Net Price, Complete with Equipment $48.00

WEAVER Auto Ambulance

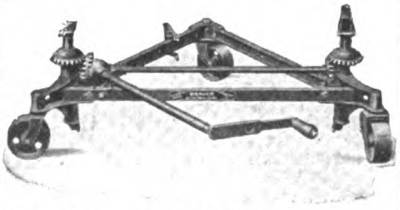


FOR CRIPPLED CARS

A thoroughly substantial and practical device for towing in disabled cars.

Strong, compact, comparatively light, enables one man to do the work of three.

Roller Bearing Cast Steel Wheels; Telescoping steel tongue; 1¼ inch steel axle; full range of adjustment.



LIST PRICE, $30.00

WEAVER Auto Twin-Jacks

The one piece of equipment which enables one man to manipulate a car upon the floor in any desired manner.

Ball and roller bearing casters and lifting mechanism will handle extremely heavy loads with ease.

It's the cuts and holes in casings you must watch and repair, if you want the mileage you are entitled to out of your tires.

TIRE-DOH

is the best and easiest-to-use repair made for sealing up casing cuts and holes. It keeps out the water and dirt that rot and wreck the fabric. It is a marvel not only for preventing casing blowouts, but also for repairing them after they occur.

Anyone can easily repair damaged casings with Tire-Doh, and a repair thus made is good for hundreds of miles—for Tire-Doh after setting becomes as tough as the tire itself, and lasts—for

TIRE-DOH REPAIRS ARE PERMANENT REPAIRS

On account of its plasticity, Tire-Doh can be used to make repairs that are inaccessible to other repair methods.

Tire-Doh is particularly effective for repairing all inner-tube punctures and blowouts. It repairs easily and permanently the pin-point hole, or the tear as long as your arm—does it without heat or tools—anywhere—on the road or in the garage—and any time. The average inner-tube puncture repaired with Tire-Doh costs less than 2 cents.

WE MANUFACTURE
18 Other Tire-Doh Products
All As Good As TIRE-DOH

Atwater Kent

for Fords

During the last two years there has been a very rapid change by car manufacturers from the magneto type of ignition to the Atwater Kent System.

One-quarter of all 1915 "Made-in-U. S. A." cars (exclusive of Fords) will be Atwater Kent-equipped. Tens of thousands of Ford owners, by following the example of a hundred thousand enthusiastic Atwater Kent users, will discover for the first time the flexibility, power, speed and economy of which their motors are capable.

The Ford motor not only starts more easily, idles much more slowly and quietly and pulls harder and longer at all speeds, but its performance is better at every point of running. Gasoline economy is improved at least ten per cent., less carbon is deposited and acceleration is far more rapid.

The control of the spark is automatic, giving a positive retard for starting and advancing the time automatically and accurately to suit all running speeds.

The Atwater Kent System produces a single hot spark, timed with perfect synchronism and absolutely uniform, no matter whether the motor is being cranked or is running at top speed. A push button on the coil produces an extra hot, flame-like spark for starting "on compression."

Atwater Kent Ignition does not belong to the host of low-priced Ford "specialties"; it is unquestionably the best ignition equipment that money can buy, whether for a Ford or a Packard.

Become familiar with the famous Atwater Kent principle by sending for and reading the interesting descriptive booklet written especially for Ford owners, and then demand that your dealer show you the real Atwater Kent System.

TO DEALERS:

Every Atwater Kent Ford System which you sell adds another enthusiastic customer to your list. Atwater Kent Ignition is well and favorably known throughout the entire automobile field and is widely advertised in leading publications. Over five thousand well-known and prosperous dealers, jobbers and repair men throughout the country are specializing on Atwater Kent equipment. Are you getting your share of this business? Write today for the interesting and attractive booklet telling about the Ford System.

"Just Like a Mirror!"

JOHNSON'S PREPARED WAX

is the standard polish for body, hood and fenders. It is quite **different from** the many liquid polishes on the market—most of **which contain acid or oil, and if they do not actually injure the finish—at least remain on the surface sticky and tacky—gathering every bit of dust.**

Johnson's Prepared Wax is not a new product—it has been on the market for twenty-five years. It is used every day in thousands of homes for polishing pianos, fine furniture, woodwork and floors. Our cherished reputation stands back of Johnson's Prepared Wax.

Send us the attached coupon together with 10c and we will forward postpaid a can of Johnson's Prepared Wax—sufficient for one application on a large car.

Agents wanted to sell Johnson's Prepared Wax.

S. C. JOHNSON & SON
"The Wood Finishing Authorities"
RACINE, WIS.

Johnson's Prepared Wax **cleans, polishes** and **finishes** in one operation. It preserves the varnish and protects it from the weather. It is in paste form—clean and easy to use and economical.

Does Not Gather Dust

Johnson's Prepared Wax gives a perfectly **hard, dry, glasslike** finish that cannot collect dust. It forms a thin, protecting film over the varnish—prevents checking and cracking and

"Sheds Water Like a Duck's Back"

It keeps **new cars** bright and good looking for an indefinite time—and will make **old cars** look as well as a coat of paint and varnish. Mud spots can be easily and entirely removed from cars which have been polished with Johnson's Prepared Wax. It imparts a velvety, protecting finish of great beauty and durability. It is impervious to dust, water, scratches, finger prints, etc.

1 pint by Parcel Post 60c—enough for a season's use.

I enclose 10c for a can of Johnson's Prepared Wax—sufficient for one coat on a large car.

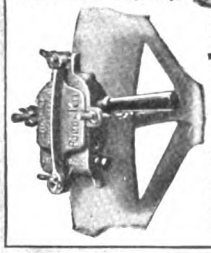
Stop the Hole—Save the Tire

Like a "stitch in time saves nine" so vulcanizing the small hole saves the blow-out later on.

These small holes when neglected expose the fabric. Sand blisters form. Water and moisture ooze through and rot the fabric. Then comes the blow-out—a big repair bill and usually a ruined tire. Stop this needless trouble and expense.

You can save your tires, save repair bills, increase your mileage and prevent tire trouble by vulcanizing the smal cuts and holes with a Shaler Vulcanizer You can keep your tires in perfect condition all the time.

SHALER Vulcanizers



Increase Your Mileage—Save Repair Bills—Prevent Roadside Delay

SHALER

Tube-Kit $2.00

Does away with temporary patches for repairing tubes. Can be carried in the tool box for roadside repairs or can be used indoors. Is free from soot and smoke and the fuel cannot spill and flare up. Handle is detachable. Complete $2

SHALER

Ford-Kit $2.75
For Ford Tubes and Casings

This model, designed especially to fit Ford tires, makes every practicable tube and casing repair. Safe, simple, clean—no exposed blaze

will repair any puncture, rip, cut, tear or hole in casing or tube in a few minutes and make the repair the strongest part of the tire.

The Shaler is simple and easy to use. Anyone who can drive a car can easily and quickly vulcanize any tire with a Shaler. It requires no watching or regulating. You do not have to fear overcuriug or undercuring the rubber. The Shaler has an **automatic heat control** which provides the exact heat for perfect vulcanization—no more—no less. Shaler vulcanizers are standard. Their principle is correct.

We are the world's largest makers of vulcanizers and make a complete line for every need, in every type—Alcohol—Gasoline—Steam or Electric. We make small portable outfits for tourists—Tube Kit, $2.00, (for vulcanizing tubes), Ford-Kit, $2.75, (for Ford owners), Vul-Kit, $3.50, (To carry in tool box for roadside repairs to tubes and casings), Model D, $12.50, (Electric outfit for private garages) and Garage Outfit at $60.

Get This Book Free
"Care and Repair of Tires"

"Care and Repair of Tires" tells the proper inflation you should maintain in your tires according to weight, load and seasons. It describes fully how to protect the tires while car is idle in the garage—how to care for them in winter and extreme hot weather—how to avoid substances that rot the rubber and fabric. It gives splendid hints on the spare tire and its care—how to carry extra tubes. It is really a text book on the care of automobile tires. It also describes each Shaler Model in detail and explains how it operates.

To Dealers—Garages and Repair Shops

Garages can add $20 or more a day to their profits vulcanizing tires with Shaler Vulcanizers. Accessory dealers can greatly increase their sales and profits selling portable Shaler Vulcanizers to motorists. Every repair shop should have the Shaler Garage Outfit. Every accessory dealer should stock the tourist Shalers. Use the coupon today. Get our interesting proposition and read our free book "Common Sense About Tire Repairs" (for dealers only).

ANNOUNCING
The New FORD Model

Brad-Kent Carburetor

Patents Allowed

The *Brad-Kent* is the most efficient carburetor made today. Every test has proved its superiority to all other types—in ease of adjustment, quick starting, power, speed and economy of fuel.

And now we announce the new FORD Model. Where others promise—we guarantee. Every *Brad-Kent* Carburetor is guaranteed to live up to the statements made in our advertising matter. Prove it on your own car at our risk.

Adds 5 Extra H. P.

No matter what your present carburetor—we guarantee the *Brad-Kent* to increase the available power of your engine by at least 5 h. p.

It makes a quicker get-away, climbs hills more easily, and carries you through the hard places that stop you now.

And this extra power costs you nothing.

Gives 10 Miles Extra Speed

The *Brad-Kent* will get greater speed out of your Ford motor than any other known carburetor. This we guarantee and your speedometer will prove it. You may not need this extra speed often—but it's there when you want to use it.

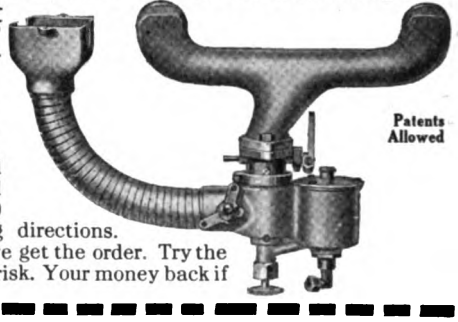
And this extra speed costs you nothing.

Saves 2 Gallons Out of Every 5

Replace your present carburetor with a *Brad-Kent* and we guarantee that it will take you as far and as fast on three gallons of gasoline as you formerly traveled on five gallons.

In a recent official test conducted by Mr. F. E. Edwards, Official Observer for the Chicago Automobile Club—a fully equipped Model T Ford was driven over country roads for 102.1 miles—at an average gasoline consumption of *1 gallon for 33.12 miles.*

THE FROST MFG. CO., Kenosha, Wis.



One Adjustment Only

The advantages we guarantee are far below best actual records for *Brad-Kent* Carburetors. You run no risk of disappointment, because our sweeping guarantee is backed by ample resources and responsibility. We refer you to Dun, Bradstreet, or any banker. And we run no risk in making this guarantee, because we know that the *Brad-Kent* is without an equal.

It is the only truly efficient and reliable carburetor having but a single adjustment. Much lighter and less complicated than other good carburetors. Built on an entirely new principle. Easiest to start in cold weather. But results count. And the *Brad-Kent* is guaranteed to give results.

30 Days Free Trial

The special Ford Outfit includes the carburetor, manifold, hot air tube and stove. It fits any Ford car and can be easily installed. The special introductory price for this complete outfit is but $12.50—money back if not satisfied. *$15.00 after June 1st.* For this small investment you get at least *5 extra h. p.*, at least *10 miles more speed*, and a saving of *2 gallons of gasoline out of every 5 that you now buy.*

Patents Allowed

Try It On Your Car

Mail the attached 30-Day Approval Blank with $12.50 and your shipping directions. We'll ship the day we get the order. Try the *Brad-Kent* at our risk. Your money back if you return it for any reason within 30 days. Get our interesting booklet. **Dealers:** Write for special proposition, prices and a sample *Brad-Kent* Ford Outfit on 30 days approval.

30-Day Approval Blank

THE STAUDE GLARE STOPPER

Without the Staude Glare Stopper—driving ahead in the glare like a blind man.

Protected by the amber glass of the Staude Glare Stopper—this driver sees exactly where he is going.

THE Staude Glare Stopper consists of a disk of pure amber glass, easily attached to the windshield of any make of car. It protects the eyes of the driver from bright and blinding lights, both by day and by night.

You may be able to sell dimmers for headlights where the law demands them, but the Staude Glare Stopper corrects the trouble at the right end, protecting the driver rather than reducing the light. You will find that the Staude is the only real practical solution of the danger from night driving.

The Staude Glare Stopper has been used in different experimental forms in the Twin Cities for over a year. This new model is the permanent development of experience.

The Staude can be adjusted to any make of windshield and clamped at the top or side for either a right or a left hand drive. It is easy to place, fits snug, and looks trim.

A specially designed joint in the arm allows the Staude to be kept perpendicular at all times without regard to the angle of the windshield. The heavy amber colored crystal lens glass is 6⅞ inches in diameter and is specially ground and polished.

(Patent Applied For)

The Staude Glare Stopper

The nickel plated clamp will fit on the windshield of any make of car. The heavy clear amber-colored crystal lens glass, 6⅞ inches in diameter, dissects the light rays and makes driving at night a constant pleasure instead of a constant fear

Retail Price

$2.50

THE Staude is sold on an absolute money-back guarantee. Every dealer is instructed to refund the full purchase price to anyone who, after using it, does not agree that it does everything we claim for it.

The Staude looks like a $5.00 automobile accessory. But, as we believe, within a short time no driver will any more think of doing without a Staude than he would doing without a horn, we have placed the retail price at $2.50 and still allow a liberal margin of profit both for dealers and jobbers buying in large quantities.

As the Staude is such a noticeable and distinctive part of a car, to be the first to introduce it in your city will be one of the best advertisements you can have. Everyone is talking about the Staude. We are planning an extensive consumer advertising campaign.

Write us today for prices.

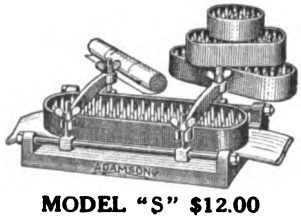
ADAMSON
VULCANIZERS



MODEL "U" $3.00

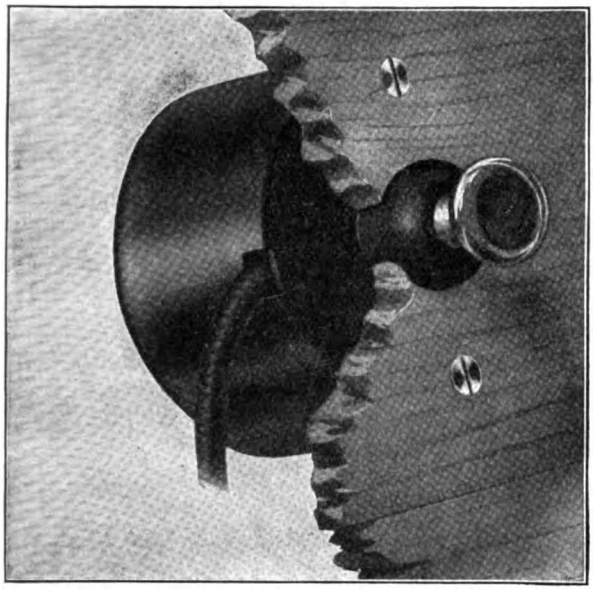
MODEL "T" $2.00

MODEL "M" $1.50

MODEL "S" $12.00

90% of tire troubles are saved by the use of an ADAMSON VULCANIZER "in time". The use is a simple process. No steam or electricity --no watching or regulating--it's automatic.

The simplicity of Adamson Vulcanizers and their very low cost, added to the INSTANTLY SATISFACTORY results secured from their use, has gained for the entire line a tremendous popularity. This, however, has only begun. Travel during 1915 will be the greatest ever! People will explore their own country. More than ever will they CONSIDER a practical Vulcanizing outfit---for the motorist wants to make repairs **"on the spot"**. That's why the ADAMSON is necessary. It makes instant repairs, regardless of where he may be, without trouble or danger, and at trifling expense. A quick, slick, permanent job---VULCANIZED, not "patched".



The ADAMSON is not an experiment, but the most extensively used Vulcanizer today. Over half a million motorists carry it in their tool kits---and they wouldn't think of starting a trip without it. It is, however, a distinctive Vulcanizer,---unlike all others and protected by patents. It is so simple, practical, certain in its operation that nothing equals it. And its price! It's so low that a motorist can't find an excuse for not buying it. It's the cheapest tire insurance obtainable.

There's a big opportunity for you to make good profits right **now** selling the ADAMSON. Its low price, great reputation and many advantages make sales come easy. Better start today.

Dimmer attached to footboard

Dim Your Lights with a Touch of Your Foot

The H.P.B. Kick-Over Dimmer

The H. P. B. KICK-OVER is a switch, which when attached to the floorboard, footboard, or dash of your automobile will dim your headlights or change from headlights to sidelights by a slight pressure of your foot on the protruding knob. Kick the knob again and the headlights are on with their full power.

Why lean over and fumble for a lever or push button every time you want to dim you headlights? *Use your idle left foot.* The H. P. B. is simple and compact, and can easily be attached to *any* electrically lighted car with about one hour's work.

Dealers:—Write to the manufacturer for local advertising proposition.

Trade Mark

"NO-LEAK-O"

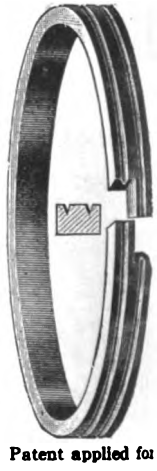
A Scientific Oil Packing Piston Ring

A RING WITH A REASON

There's no mystery about "NO-LEAK-O" rings. A simple, plain, mechanical fact.

Piston movement, uneven expansion and contraction, makes perfect fitting impossible. It's the OIL that forms the seal, prevents escape of gas and lubricates.

It is only a question of how to keep a volume of oil between the rings and cylinder-wall, without waste. There's but one way; that's our way. Make oil grooves around the rings; simple, isn't it?



The grooves convey enough OIL to form the seal, which means perfect compression without WASTE; maximum power with less GASOLINE; perfect lubrication without CARBON, smoke, and oily plugs.

We absolutely guarantee each ring for QUALITY, ACCURACY, and satisfactory service.

One Piece, Low Cost, High Efficiency.

Carbon Eliminated by Controlling the Oil.

Big Money to Garages

A new source of big revenue for garages is opening up in the rapidly increasing use of ELECTRICAL STARTING AND LIGHTING EQUIPMENT, with the consequent necessity for repairs and adjustments, etc.

Are you prepared to handle this trade? Certainly not, if you are not properly equipped. If you go at it by hit-or-miss methods you will drive away your trade, and it will carry with it the general repair and supply trade of all kinds.

It is absolutely necessary that you be equipped with a

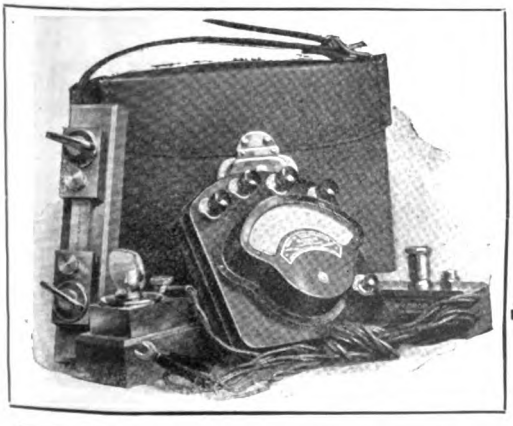
Weston

GARAGE TESTING INSTRUMENT

Model 280

A thoroughly reliable instrument of precision offered in a convenient size and at a price that enables you to obtain a full and permanent Electrical Testing Equipment at an insignificant cost.

In reality this instrument is the equivalent of six separate electrical measuring instruments of different ranges, and it provides a means of making any tests that are necessary on Electric Starting and Lighting Systems



If you want to control the cream of high-class trade in your territory, write to us at once for our SPECIAL PROPOSITION.

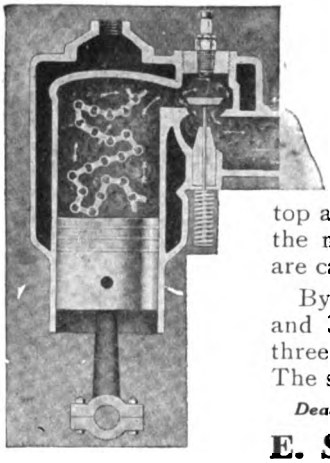
JOIN THE "CHAIN GANG"

IT WILL SAVE YOU TIME AND MONEY

You don't clean your watch with a hoe, nor do you hold it over a flame to burn out the dirt. Why? Because your good common-sense tells you not to.



75c Each Insured
3 for $2 Postpaid

But how about the cylinders of your engine, with their polished surface and delicate adjustments? Do you allow the *hoe* or the *flame* method to be used when you have the carbon removed?

If you have the motor torn down, the adjustments and gaskets are disturbed. Or if the oxygen process—the "burn out the dirt" method—is used, you run two risks: (1) that of setting fire to the car, (2) that of cracking or warping the cylinder walls with the intense heat, which also destroys the lubrication of the cylinders.

TRY the Michener way,—the quickest, most efficient, cheapest, and the one absolutely harmless method of removing carbon. And—here's the point—with the **Chain Carbon Remover** you can do the cleaning yourself, on the road or in the garage, **in 20 minutes.**

Simple as A B C to use: the Chains are inserted through the spark plug holes, ignition cut off cylinders being treated, and the motor is run slowly for about three minutes with power from the remaining cylinders. The Chains are then readily removed with the hook which is provided for this purpose. The striking of the Chain upon piston head, top and sides of cylinder, as it is tossed about by the moving piston, loosens all deposits, which are carried off through the exhaust ports.

By using 2 Chains in a four cylinder motor, and 3 Chains in a six cylinder motor, two and three cylinders can be cleaned at one operation. The same Chains may be used again and again.

Dealers' Proposition Especially Attractive. Write for It.

E. S. MICHENER, JEFFERSON ST., NEW CASTLE, PA.

WARNING—*The making, vending, using or having in one's possession a chain of any description—other than the Michener chain—for the purpose of removing carbon deposits from cylinders, is an infringement of patents held by me and will be prosecuted.* E. S. ICHENER.
